INDEX TO VOLUME CXXIII.

- Abbe, R.** Spinal surgery, a report of eight cases, 63, 86.
Abbott, S. L. Cases of cystitis treated with salol, 67.
Abbott, S. W. What constitutes a fifth-disease? 62.
Abdominal Surgery. Large papillomatous cyst with ascites, laparotomy and removal of tumor which lay unusually high, nature of it with complete recovery, Cope, A. L., 89; an unsuccessful case of digital dilatation of the pylorus for cicatrical stenosis, Cutler, E. G., and Richardson, M. H., 581, 592.
Abortion. Treatment of abortions, Baldwin, H. C., 423.
Abscess. The nature of cold abscess without drainage, with report of cases, Lovett, R. W., 272.
Africa. A physician's notes on Central Africa, 45.
Allen, C. W. The treatment of erysipelas, 255; aristol, 255.
Allen, G. W. Some points in the treatment of gonorrhoea, 121, 132.
Altheoeffer. Perfusion of hydrogen as a disinfectant of water, 47.
Amputation. An amputee for sepsis, Porter, C. B., 181; amputation as an orthopedic measure, Vandam, A. M., 360; double primary and actually synchronous amputation of the lower extremities, with recovery, Irish, J. C., 616.
Anæmia. On the treatment of anæmia, 280.
Anæsthesia. The value of primary anesthesia in minor surgical operations, Harrington, F. B., 434.
Anatomy. Demonstration of some special characteristics in the brain of a distinguished scientist, Wilder, B. J., 89; the scope and the teaching of human anatomy, Dwight, T., 331, 339; recent progress in anatomy, Dwight, T., 391.
Anderson, J. W. Purulent ophthalmia, 159; cystlike bodies of the conjunctiva, 159.
Antiseptics and anesthetics at Berlin. 234; antiseptics and asepsis in surgery, 255; antiseptics and ether, Coggan, E., 358; the comparative value of iodide of bismuth in the treatment of surgical antisepsis, Jewett, C., 442; the application of antiseptic antisepsis in midwifery practice, McMurry, L. S., 448; disinfection of the hands, Ball, 452; wet antiseptic dressings in injuries of the hand, Nicolson, W. F., 568.
Anus Medicum MDCCXC, 622.
Apparatus for artificial respiration. Recovery, Stedman, C. E., 290, 302; appendicitis, operation, Garceau, E., 483; appendicitis, Gay, G. W., 557; appenditiis, typhilitis and perityphilitis in children, Smith, J. L., 561; two cases of relapsing appendicitis, operation between attacks, removal of appendix, recovery, Porter, C. B., 610.
Armistice. The effect of our neutrality in the War of the Rebellion, Lyman, G. H., 16, 169; the new status of the army, the fifth distribution of arms and legs to veterans, 333; an army surgeon's tour of duty with State troops, 574.
Arsenic. The hypodermic use of arsenic, Moyer, H. N., 447; a case of multiple neuritis due to arsenic, E. C., 464.
Asch, M. J. A new operation for deviation of the nasal septum, 12.
Ashby, T. A. Laparotomy for intra-pelvic pain, 444; drainage after laparotomy, 422.
Atkins, E. C. Asylums as a health resort, 390.
Attitudes in Anatomy. 390.
Babinzky. Erysipelas as a cure for diphtheria, 453.
Bacillus. The poison of bacilli, Brieger and Fraenkel, 430; tubercle bacilli, Gibbs, H., and Sharly, E. L., 487; clinical value of the bacillus of tuberculosis, Stone, A. K., 515.
Barker. Address before the American Public Health Association, 520.
Baldwin, H. C. Treatment of abortions, 423.
Baily, J. M. Ectopic pregnancy, 351.
Ball. Disinfection of the hands, 452; breaking the opium habit, 477.
Barclay, R. Dr. Blake's paper disk, case history, 113.
Barry, G. Poisoning in the Bonapart presidency, 291.
Baxter, G. A. Silicate of soda, some new methods of use in surgery, 569.
Beach, H. H. A. A neuroplastic operation, designed for the restoration of nerve trunks that have been destroyed by injury or disease, 562.
Becker. A new and rapid test for sugar, 309.
Belfield, W. T. Notes on the technique of suprapubic cystotomy and prostatectomy, 15; résumé of experience to date, all over the world, in the various operations for cystitis from prostatic hypertrophy, 447.
Beri-Beri. Multiple neuritis or beri-beri among seamen, Putnam, J. J., 62; a form of polyneuritis, probably analogous to or identical with beri-beri, occurring in seafaring men in Northern latitudes, Putnam, J. J., 244; beri-beri on fishing vessels from the Grand Banks, 497; cases of beri-beri occurring in the Provincetown Grand Bank fishing fleet, Birge, W. S., 464.
Berlin. The Berlin International Congress, 188, 212, 213, 214, 227, 228, 229; the Berlin water and sewage works, 189; antiseptics and anesthetics at Berlin, 234; en route to Berlin, 326.
Bibliography. Allingham, H. W., the treatment of internal derangements of the knee-joint by operation, 163; American Surgical Association, transactions, Vol. 11, 449; Ashurst, H. Jr., the principles of children, medical and surgical, 230; Ashurst, H. Jr., the principles and practise of surgery, 185; Ashton, W. E., Saenger's question compendium, No. 5, 207; Association of American Physicians, transactions, IV, 229; Boston College of Physicians, including organization, 271; Bullock, E. C., a handbook of obstetric nursing, a brief description of the succession of plants in geologic time and a glossary of botanical terms, 446; Bernheim, H., suggestive therapeutics, a treatise on the nature and uses of hypnotism, 65; Bourville and others, recherches cliniques et therapeutiques sur l'épilepsie, Paris, 1895, 116; Braine, J., a treatise on the diseases of nerves and their surgical treatment, 164; Bradford, E. H., and Lovett, R. W., a treatise on orthopaedic surgery, 186; Doty, A. H., a manual of instruction in the principles of prompt aid to the injured, designed for military use, 186; Dryer, J. C., a manual for physicians for military use, 186; Elmer, J. C., a manual for physicians for military use, 186; Evans, J. C., a manual for military use, 186; Fink, A. M., a handbook of obstetric nursing for nurses, students and mothers, 230; Garretson, J. A., a system of oral surgery, being a treatise on the diseases and surgery of the mouth, jaws, face, teeth and associate parts, 461; Graham, D., massage kraft transmitteling, 185; Heath, C., a manual of minor surgery, 185; Hirsch, J. C., a manual of obstetrics for junior practitioners, 163; Hirst, B. C., a system of obstetrics by American authors, 506; Hurd, E. P., a treatise on neuralgia, 164; James, W., the principles of psychology, 356; Keating, J. M., cyclopedic guide to the diseases of children, medical and surgical, 17, 621; Kraft-Ebing, R. von, an elementary treatise on the domain of hypnotism, 17; Massachusetts Board of Health, report, 647; Messey, G. B., electricity in the diseases of women, 207; Maxwell, T., terminologic medico polyglotta, 256; medical bulletin visiting list, 622; Morris, M., international atlas of rare skin diseases, 400; Norment, J. L., a manual of the diseases of the eye, 186; Obersteiner, H., the anatomy of the central nervous organs in health and disease, 187; Osler, W., the cerebral palsies of children, 229; Owen, E., a manual of anatomy for senior students, 231; Page, R. C., a hand-book of practical diagnosis of diseases of the heart, 236; Peñalosa, A., a physician's all-round time- and labor-saving account book, 246; Senn, N., surgical bacteriology, 183; Sevestre, études de clinique infantile, 230; Shoemaker, J. V., ointments and olesates, especially in skin diseases, 401; Sterling, W., outlines of practical histology, 262; Tavel, L., a manual of the diseases of the eye, 186; Whipple, H. H., the Gustonian lectures on secondary degenerations of the spinal cord, 114; Watson, B. A., an experimental study of lesions arising from severe concussion, 229.
Bigelow, H. J. 450, 474, 481, 482, 534; the memorial meeting of the Boston Society for Mental Improvement, 503; Bigelow as a surgeon, Cabot, A. T., 510; Henry Jacob Bigelow, M.D., Fitz, R. H., 511; Dr. Bigelow and the introduction of ether, Plino, P., 554; the claim that the merit of introducing ether belongs to Dr. Henry J. Bigelow, Dwight, T., 553; resolutions of the Medical Board of the Massachusetts General Hospital, 511.
Blanchard. Allard, C. L., 48; Allen, J. A., 216; Batchelder, D. H., 241; Baxter, J. H., 210, 578; Bigelow, H. J., 450, 474, 480, 553, 554, 602; Bishop, F. H., 360; Blakeman, W. N., 189; Borland, J. N., 189; Brock, C. L., 189; Culbertson, H., 24; Davidson, H. E., 190; DeWitt, T. K., 489; Dohme, C. W., 189; Dryer, J. C., 156; Dryer, J. C., 454; Grimes, T. T., 216; Griscom, J. D., 144; Gruber, W., 404; Hardy, E., 404; Hubbell, C. L., 300; Kingsley, G. L., 336; Lehman, G. C. H., 404; Lewis, R. J., 504; Mawaroring, R. A., 264; Meeker, C. D., 336; Murphy, J. C., 283; Monod, G., 649; Niles, D. W., 96; Nuttall, W. C., 189; Parker, C. C., 189; Peacock, J. C., 189; Peacock, J. D., 226; Roberts, J., 120; Sharp, J. C., 300; Smith, W. E., 72, 149; Spring, C. E., 422; Starr, J. H., 146; Stevens, W. F., 264, 336; Stewart, J. L.,

INDEX TO VOLUME CXXIII.

- 604; Swett, Samuel, 580; Taylor, J. H., 408; Thayer, P., 360; Thomson, C. S., 192; Vogel, A., 548; Wilmarth, J., 360.
- Birdsall, W. R.** Remarks on therapeutics as applied to nervous disease, 11.
- Birge, W. S.** Cases of beri-beri occurring in the Provincetown Grand Bank fishing fleet, 461.
- Blake, C. J.** The Boston City Hospital, 1.
- Blodgett, J. L.** The use and implications of oxygen in cases of blood-poisoning otherwise fatal, and in other diseases, 481, 493.
- Blood.** The pathology of the blood, 498.
- Boldt, H. J.** Inoculations for pulmonary tuberculosis, 567.
- Bone.** Osteo-chondro-myxoma of the right thigh, Whitney, W. F., 85; some observations on bone and skin grafting, Cavana, M., 563.
- Bordet.** On the transmission of typhoid fever by the air, 141; mumps, 477.
- Boston City Hospital, Blake, C. J. I.**
- Bosworth, F.** A case of unilateral paralysis of the abductors of the larynx, the result of an attack of bulbar disease, with unusual symptoms, 36.
- Bouyoucos.** Paroxysmal pulmonary edema in chronic albuminuria, 211.
- Bowen, J. T.** Cases of cutaneous tuberculosis with histological studies, 254; report on progress in dermatology, 362, 589.
- Brown, E. G.** The treatment of lateral curvature, 250, 327; the treatment of deformities of spastic paralysis, 363; the surgical treatment of spastic paralysis in children, 485.
- Bradford, E. H., and Lovett, R. W.** Report on the recent progress of orthopedic surgery, 439, 441; congenital deformity of the nose, 586.
- Brown, E. B.** A study on pruritus, 233.
- Brown, B.** The local and general treatment of gangrenous wounds and diseases, 345.
- Brown, F. T.** A case of severe hematuria, nephrectomy by Dr. McMurtry, 400; removal of a tumor, 366.
- Brown, J.** Facial and pharyngeal tenesmus, 477.
- Buchner.** Pyrogenic material within bacterial cells, 551.
- Buck, A. H.** On the renewed employment of the nasal douche and kindred procedures, 111.
- Buckingham, E. M.** Influenza in the out-patient service of the Boston City Hospital, 343, 348; unnecessary noise an avoidable evil in cities, 436.
- Bulkeley, L. D.** Clinical notes on lichen planus, 495.
- Bull, C. S.** The extraction of dislocated lenses from the eye, whether transparent or opacified, 126; some further considerations on "simulated" formation of cataract, 126.
- Burnett, C. H.** Permanently good results of excision of the maxilla and membrana tympani in a case of chronic tinnitus and aural vertigo, and in a case of chronic suppuration of the attic due to necrosis of the malleus, 112.
- Burnett, C. H.** Another needle forceps, 274.
- Burrell, H. L., and Cushing, H. W.** Report on recent progress in surgery, 319.
- Bursa.** A case of enlarged subcutaneous bursa in front of the tubercle of the tibia, Monks, G. H., 591, 592.
- Bystrom, E.** Vaginal fixation of the stump abdominal hysterectomy, 388.
- Cabot, A. T.** A case of exostosis, with the formation of a thick epidermal sheet in the bladder, 11; a case of cyst of the kidney apparently cured by a single aspiration, 39; a case of extraprophyxial bladder, 11; a case of large paramecium cyst, 11; a case of acute laparotomy, wound of the bladder which lay unusually high, situated, with it complete recovery, 83, 84; piece of catheter in the bladder, 84; a new case of uretero-lithotomy for an impacted calculus, 247; old anterior dislocation of the humerus, 292; dorsal cyst of the ovary, 278; a case of a tumor of the outer epiploic border, 43; Billroth surgeon, 510; notes on the non-operative treatment of enlarged prostate, 539, 537; another successful case of uretero-lithotomy, 613.
- Caldwell, W. H.** Rectal medication, 570.
- Cancer.** Recent speculations as to the nature of cancer, the electrolytic treatment of cancer, 19.
- Carman, W. H.** A contribution to ocular tumors, 169.
- Carpus.** Forward dislocation of one of the carpal bones, Cabot, A. T., 443.
- Cavino, M.** The physician as a witness, 523.
- Cecocutaneous.** Manipulation of the nasal mucous membrane, 577.
- Cephalhematoma.** Kelly, H. A., 421.
- Chadwick, J. H.** Two cases of hidatidiform mole, 423; two cases of tumors coincident with pregnancy, 424; choristoma of potassium as a preventive in malignant death, 424; two cases of pregnancy complicated with tumors, 522.
- Chancellor, C. W.** How diphtheria is spread by corpses, 166.
- Chancery.** Curetting the soft chancre, Petersen, 476.
- Chandler, H. B.** Report of fifty cataract extractions by a new method, 362.
- "Chancery doctors," 19.
- Chapin, H. S.** Hygiene in the public schools, 472.
- Chase, W. D.** Diffuse calcification of the muscular system in a case of fracture, 158.
- Childs, W. R.** Report on medical chemistry, Hills, W. B., 6.
- Children.** Report on diseases of children, Rotch, T. M., 163, 387, 614; pericarditis in childhood, Knoff, 380; stomach washing in very young children, Froitzky, 453; the surgical treatment of spastic paralysis in children, Bradford, E. H., 483; appendicitis, typhilitis and pyphilitis in children, Smith, J. L., 564; hydrocoele in children, with a report of cases, Lovett, R. W., 584, 592; Boston Children's Hospital, 600.
- Child-wife murder,** 332.
- China.** Chinese medical practice and practitioners, Thomson, J. C., 501.
- Chloroform.** Decomposition of chloroform by artificial light, Kunzal, 453.
- Cholera in Spain.** Santa, D. P., 94; cholera in Spain, 261.
- Chorea.** Unusual forms of chorea, possibly of spinal origin, Mitchell, S. W., 419; C. H. 41.
- Circumvallate papillae.** Cases of large, pulsating arteries on the posterior wall of the pharynx, Farlow, J. W. Jr., 61; a case of malignant endocarditis secondary to colitis, remarks, Shattuck, F. C., 79, 84; malignant endocarditis, death, autopsy, Siezman, C. E., 84; circumscribed dysrhythmia, 91; the causality of cardiac disease, 111; heart failure, Whittier, F., 282; 220; hematomas of the sternocleidomastoid muscle, Judson, A. B., 274; a case of considerable cerebral hemorrhage without symptoms, Shattuck, G. B., 324; pericarditis in childhood, Knoff, 380; torsion of arteries as a means for the arrest of hemorrhage, Murdoch, B., 420; cephalhematoma, Kelly, H. A., 421.
- Cleverley, R. V.** Erichsen's disease as a form of the traumatic neuroses, 217.
- Climate.** Some of the relations of climate to health and disease, Smith, W. E., 149, 173; is the mortality after gynecological operations affected by climatic influences? Cox, H. C., 421.
- Club-foot.** The mode of dealing with club-foot, Morton, T. G., 327.
- Couts or shirt-sleeves,** 68.
- Cough, W. H. H.** Suprapubic cystotomy in a case of enlarged prostate, 544.
- Cocaine analgesia,** its extended application in general surgery, when hypodermically employed, 48; laparotomy under cocaine, 361.
- Coccydynia.** A case of coccydynia, removal of coccyx, recovery, Post, A., 360.
- Cox, H. C.** Is the mortality after gynecological operations affected by climatic influences? 421.
- Coffee.** Love, I. N., 418.
- Coggins, D.** Iodide of sodium and iodide of potassium, 47; antiseptics and ether, 358.
- Cohen, S. S.** Look beyond the nose, II. Colles' fracture, with especial reference to treatment, Huse, R. C., 72.
- Colorado** as a health resort, Atkins, E. C., 390.
- Colt, H.** Obstetrical work in a cottage hospital, 386.
- Conn, G. P.** Railway hygiene, 155.
- Consumption in Massachusetts.** French, J. M., 340; Stetson, G. R., 451.
- Cook, G.** Three cases of surgery, 157; a case of rhinoplasty, 226.
- Corlett, W. T.** A clinical study of perianal hernias, winter itch, frost itch, etc., 253.
- Coroner.** The medical examiner vs. the coroner, 200.
- Cottage hospitals.** Obstetrical work in a cottage hospital, Colt, H., 388; the responsibilities and legal dangers of cottage hospitals, 425.
- Cutting, B. E.** Cases in which the disease indicated by the symptoms is not the main symptom examination, why doctors may be non-committal sometimes, 431.
- Cough.** Its relation to intra-nasal disease, Thrasher, A. B., 419.
- Country doctor,** 42; Wilmarth, J., 142; road-help for the country doctor, Potter, 551.
- Cradectomy for microcephalic cretinism,** Wendt, E. C., 238.
- Cranectomy for microcephalic cretinism,** Wendt, E. C., 238.
- Cronyn, J.** Prognostics in medicine, 468.
- Cushing, B.** A case of obstruction of the bowel, 326.
- Cushing, E. W.** The Berlin Congress, 214, 282.
- Cushing, E. W.** System of obstetrics in a negro, Forster, L. J., 58; addressed before the American Dermatological Association, Morrow, P. A., 252; observations on prurigo, clinical and pathological, Taylor, R. W., 253; a clinical study of pruritus, hematocele, winter itch, frost itch, etc., Corlett, W. T., 253; cases of cutaneous neoplasms, 254; a case of trichoblastoma, 255; remarks on the treatment of dermatitis herpetiformis, Dubring, L. A., 254; a case of atropia muculosa et stricta following typhoid fever, Shepherd, F. J., 254; immigrant dermatoses, White, J. C., 254; a case of second infection with syphilis and a case of syphilis, 255; a case of syphilis, 256; a case of syphilis, Taylor, R. W., 255; electrolysis in the treatment of lichen vulgaris, Jackson, G. T., 255; pilon, Stetson, H. W., 255; the treatment of cryspelas, Allen, C. W., 255; aristol, Allen, C. W., 255; notes on pilocarpine in dermatology, Klotz, H. G., 255; the treatment of dermatological cases by means of radium, 256; the treatment of syphilis, 256; the use of skin from puppies in skin-grafting, Van Meter, M. E., 252; ectema from the use of creolin, 263; clinical notes on lichen planus, Bullock, L. D., 255; some observations on bone and skin grafting, Ricketts, B. M., 255; report on progress in dermatology, Egan, J. T., 255.
- Cutter, E.** A case of multiple neuritis due to arsenic, 403, 405; a case of pseudo-muscular hypertrophy in an adult, 425.
- Cutler, E. G., and Richardson, M. H.** An unsuccessful case of digital dilatation of the pylorus for cicatricial stenosis, 581, 592.
- Dalton, H. C.** Cases of penetrating stab-wounds of the abdomen, 200; rectal, rectite, 410.
- Dana, C. L.** Chronic softening of the cord, sepiile paraplegia, 42; on ingravestine apoplexy, 88.
- Dana, I. T.** Seizures characterized by shock and sudden coma, 289.
- Davenport, B. F.** Food, drugs and their adulterations, 186.
- Davenport, B. F.** Report of progress in gynecology, 128; a case of vaginal hysterectomy, 200; a case of cervical removal by vaginal lithotomy, 204; incontinence of urine due to malposition of the uterus, 426.
- Death.** The diaphanous test of death, Richardson, B. W., 332.
- Defendina.** On the fate of the human decidua reflexa, Minot, C. S., 561.
- Decollation in medical practice,** 306.
- Delavan, D. B.** On the early diagnosis of malignant disease of the larynx, 37.
- Dencke.** A case of tubercle inoculation, 381.
- Dewey, F. X.** A case of complete paraplegia cured by trephining, 61.
- Diabetes.** The treatment of diabetes, Pay, F. W., 236; the treatment of diabetes mellitus, Seeger, I., 265; a new and rapid test for sugar, Becker, 265.
- Digestive System.** An instrument for removing glandular hypertrophies from the tongue, Roe, J. O., 12; wire-loop curette for removing adeno new growth from the pharynx, Holden, E., 12; a case of stricture of the esophagus from interstitial thickening of the walls, Roe, J. O., 12; a case of acute pancreatitis, 96; observations on a case of perityphilitis, Homans, J., 202, 203, 204; a successful

- case of gastrotomy for removal of foreign bodies, Richardson, M. H., 177, 180; a piece of intestine four and half inches long with six gun-shot wounds, J. A. D. — a new method of obtaining small quantities of stomach contents for diagnostic purposes, Elshorn, M., 207; a case of gastrotomy, Gay, G. W., 221, 227; a case of ruptured intestine, Lewis, H. F., 225; two cases of laparotomy for tubercular peritonitis, Wheeler, L., 241; appendicitis, perforating, laparotomy, E. B., 242; a case of gun-shot wound of important abdominal viscera with recovery, Uriel, J. F., 318; small tumor of the upper jaw, Richardson, M. H., 325; stricture of the oesophagus, its treatment by intubation, Mixter, S. A., 326; a case of obstruction of the bowel, Cushing, H., 328; malignant stricture of the oesophagus, its treatment by Senn's method of peristomia, L. C., 329; Mixter, S. A., 325; infections dyspepsia and its treatment by the saphenous method, 417; cases of penetrating stab-wounds of the abdomen, laparotomy results, Dalton, H. C., 419; case of sarcoma of the tonsil, and its removal, Horner, J., 425; appendicitis, perforating, restoration operations involving the sphincter ani by the flap-splitting method, Hanks, H. T., 443; inguinal colectomy, Dixon, A., 446; the surgical treatment of tubercular peritonitis, 453; stomach walling up, very young children, 453; and pharyngeal tonsillitis, Browne, L. S., 454; surgical treatment of the head of the colon, McMurtry, L. S., 454; surgical treatment of appendicitis, 459; appendicitis, Gay, G. W., 457; appendicitis, typhilitis and perityphilitis in children, Smith, J. L., 454; surgery of the gall-bladder, Rockwood, E. M., 463; rectal medication, Caldwell, W. J., 478; an unsuccessful attempt to cure a case of diphtheria for cicatricial stenosis, Cutler, E. G., and Richardson, M. H., 581, 582; perforating gastric ulcer, circumscribed peritonitis, death on the fifteenth day, Fitz, R. H., 583, 585; two cases of relapsing appendicitis, operation between attacks, removal of appendix, recovery, Porter, C. B., 611.**
- Diphtheria.** The current epidemic of diphtheria in Keene, Fenner, H. K., 158; how diphtheria is spread by coryza, Chanchellor, C. W., 166; erysipelas as a cure for diphtheria, Babinsky, 433; inoculation for diphtheria and tetanus, 575.
- Dislocation.** Old anterior dislocation of the humerus, Cabot, A. T., 252.
- Dispensary, Boston, 356.**
- Diuretin.** Some new clinical experiments with diuretin, 426.
- Dixon, A.** Inguinal colotomy, 446.
- Doctor.** Country doctor, 43; doctor and druggist, 304; road-help for the poor, 130; Poor Law, 130.
- Dolan, T. M.** M. Pasteur and hydrophobia, 117.
- Donohoue, E. von.** The management of fractured limbs, 541.
- Drugs.** Food, drugs and their adulterations, Davenport, B. F., 180; changes in the tariff on drugs, 476.
- Dudley, A. P.** Drainage after laparotomy, 422; new method of treatment for retro-displacements of the uterus, with adhesions, 468.
- Dufour.** Mumps and inflammation of the lacrimal gland, 357.
- Duhring, L. A.** Remarks on the treatment of dermatitis herpetiformis, 357.
- Dwight, T.** The scope and the teaching of human anatomy, 837; recent progress in anatomy, 391; the claim that the merit of introducing ether belongs to the late Dr. Henry J. Bigelow, 553.
- Dyspepsia.** Infectious dyspepsia and its treatment by the antiseptic method, Cushing, H. F., 419.
- Ear.** Mastoid sclerosis as illustrated by a typical and fatal case, Richards, H., 110; a case in which a septum closely resembling the tympanum membrane formed in the middle third of the external auditory canal, and was removed with improvement to hearing, Thibault, S., 111; one of the first cases of mastoiditis, with pain and kindred symptoms, Bush, A. H., 111; the removal of a bullet from the ear with the assistance of the gun-barrel, Howe, L., 111; permanently good results of excision of ear, malleus and membrane tympani, in a case of chronic tinnitus and aural vertigo, and in a case of chronic suppuration of the ear due to necrosis of the malleus, Bush, A. H., 112; the Shambaugh perforated ear, Bush, A. H., 112; mastoiditis interna purulenta following erysipelas, Lipincott, J. A., 112; some cases of mastoid cell disease with a fistulous opening while recovered without the use of the drill or chisel, Pomroy, O. H., 112; mastoid first recorded in the fundus of the eye, later recorded in the nose, C. A., 112; Dr. Blake's perforator, case histories, Barclay, R. J., 113; adhesion growth in the nasopharynx, result of their removal in seventy cases of middle-ear disease, Jack, F. L., 297, 301.
- Eczema** from the use of camphor, 306.
- Electrolysis.** As a means of cure, as to the nature of cancer, the electrolytic treatment of cancer, 18; a word to young practitioners on "changing doctors," 19; the country doctor, 43; the surgical fourth, 44; recent views as to inflammation, 67; coats or shirt-sleeves? 68; cardiac dyspepsia, 91; the control of syphilis, 101; the importance of carmine, 101; some national measures of economic dietetics, 120; national measures for the prevention of food adulteration, 139; the Grand Army meeting, 164; the recognition of eye-strain by the general practitioner, 165; the diet of hot weather, 187; the Berlin Congress, 188; the Quincke disaster, 188; the functions of State boards of health, 190; the medical examination of patients suffering from chronic maladies, 209; the present state of bacteriology, 231; the physical symmetry competition at Cambridge, 237; antisepsis and asepsis in surgery, 238; post-graduate study in England, 279; on the treatment of anaemia, 280; doctor and druggist, 304; the delirium in cholera, 305; the regulation of the practice of medicine in New Jersey, 304; the pathology of inflammation, 377; a plea for conservatism in minor gynaecology, 379; oxaluria and nervous states, 403; the responsibilities and legal dangers of cottage hospitals, 425; some new medical experiments, 430; diphtheria and hot-water vapors from the Grand Banks, 427; index catalogue (volume XI) of the library of the surgeon-general's office, 448; autopsies in America, 449; obituary, Henry Jacob Bigelow, M.D., 450; the relative value of pharmaceutical and hygiene therapeutics, 473; Koch's cure for consumption, 473; Keen's treatment for tuberculosis, 497, 574, 598; the pathology of the blood, 498; the medical examiner vs. the coroner, 500; the Massachusetts health report, 547; mortality vs. immortality, 547; physical training in the Boston public schools, 548; surgical treatment of appendicitis, 548; an army surgeon's tour of duty with State troops, 574; treatment for diphtheria and tetanus, 575; etiology and treatment of epilepsy, 586; review of recent progress in medicine, 588; annals medico MDCCLXXXI, 622.
- Education.** Post-graduate study in England, 279.
- Elshorn, M.** Demonstrating a new method of obtaining small quantities of stomach contents for analysis, 207.
- Electricity.** The true position of electricity as a therapeutic agent in medicine, Prince, M., 313; electricity for rheumatism, Walton, G. L., 382; discussion on the question of amperage in the treatment of fibroid tumors by electricity, 397; the electric light as an analgesic, Von Stein, 433.
- Elwell, J.** Case of intestine four and a half inches long with six gun-shot wounds, 183.
- Empyema.** The surgical treatment of empyema, Grogan, J. A., 576.
- Endocarditis.** A case of malignant endocarditis secondary to colitis, remarks, Shattock, F. C., 59; malignant endocarditis, death, autopsy, Stedman, C. E., 82, 84.
- England.** Post-graduate study in England, 279.
- Engelmann, G. J.** The causes of ill health in American girls and the importance of female hygiene, 544.
- Encephalitis.** Atrophy of the optic nerve, enuresis, James, J. B., 261.
- Epilepsy.** The indications for trephining in epilepsy, Minor, J. C., 583; etiology and treatment of epilepsy, 596.
- Erichson's disease as a form of the traumatic neuroses, Clevenger, S. V., 277.**
- Erysipelas.** C. Rabies, 368.
- Erysipelas.** The treatment of erysipelas, Allen, C. W., 235; treatment of erysipelas, 501; facial erysipelas, 551.
- Ether.** Ether intoxication, 358; the claim that the merit of introducing ether belongs to the late Dr. Henry J. Bigelow, Dwight, C. L., 553; the Bigelow case, 553; the use of ether, Fine, P., 354.
- Everett, W. S.** A gynecological case, 31.
- Experiments.** The responsibility of the physician for experiments upon patients even with the latter's consent, 283.
- Extrauterine pregnancy.** Diagnosis, pathology, and treatment of extrauterine pregnancy, Cushing, H. F., 380; a case of ruptured tubal pregnancy, Jewett, C., 351; ectopic pregnancy, Baldy, J. M., 351; ectopic pregnancy, Kelly, H. A., 375; two cases of tubal pregnancy, Walker, E., 447; indications for operation in ectopic pregnancy, Reed, C. A. L., 545.
- Faces.** The relations to associated eye movement paroxysms, Spitzka, 589; brain tumor with interesting eye symptoms, Norris, W. F., 135; history of a case of intracranial neoplasm, with localizing eye-symptoms, position of tumor verified at autopsy, Oliver, C. A., 135; transient amblyopia with a temporal hemianopsia, a case of cerebral tumor, Cushing, H. F., 136; the relation of dislocated lenses from the eye, whether transparent or cataractous, Bull, C. S., 136; some further considerations on the "simple operation" for the extraction of cataract, Bull, C. S., 136; removal of a large exostosis of the orbit with preservation of the eye, Bull, C. S., 136; removal of a large exostosis of the orbit with the sliding flap method, Fooley, T. R., 136; case of a foreign body remaining in the eye about twenty years, followed by abscess in the scleral wall, removal and recovery, Milliken, B. L., 136; foreign body in the orbit, Morris, W. F., 137; complete paralysis of the lateral rectus muscle, a case of cerebral tumor, Cushing, H. F., 137; new tests for binocular vision, Lippincott, J. A., 137; can hypermetropia be hydrothetically outgrown? Randall, B. A., 137; treatment of muscular asthenopia and its results, Noyes, H. D., 138; legislation for the protection of the eyes, Oliver, C. A., 138; pure opium, Andrews, J. A., 139; a form of xerotic colic, Kollock, C. W., 160; two cases of glaucoma, Kollock, C. W., 160; embolism of the upper branch of the retinal artery, with normal vision, Mittendorff, F. W., 160; a case of papilledema, a case of cerebral tumor, St. John, S. A., 160; reaction to ocular tumors, Carmalt, W. H., 160; progressive astigmatism, Jackson, E., 160; three noteworthy cases of astigmatism, Theobald, H., 160; an analysis of the ocular symptoms found in the third stage of general paralysis of the insane, Oliver, C. A., 161; a new operation for sympathetic hypertension, Hinman, G. C., 161; eye strain in a penetrating wound of the conjunctiva, in which caused sympathetic neuralgia, Ristey, S. D., and Randall, B. A., 161; thrombosis of the arteria centralis retinae, a case of central retinal artery occlusion, Ferguson, E. O., 161; the recognition of eye-strain by the general practitioner, 165; diseases of the eye, and their specific treatment, 171, 172; the innervation of the ocular muscles, Wadsworth, O. F., 197; fifty-six cataract extractions by a new method, Chandler, H., 263; a case of metastatic carcinoma of the choroid, Wadsworth, O. F., 489; the therapeutics of exophthalmic goitre, Ferguson, E. O., 494; the progress of ophthalmology, Standish, M., 533; thrombotic arteritis, cerebro-arteritis, and the pial-meningo-cerebral artery, central retinal artery, Wadsworth, O. F., 559.
- Farlow, J. W.** Eight cases of large, pulsating arteries on the posterior wall of the pharynx, 6.
- Faulkner, H. E.** The great epidemic of diphtheria in Keene, 158.
- Fever.** The significance of fever, 329, 401.
- Fisher, C. I.** The necessity for social and statute recognition of syphilis, 101, 106.
- Fisher, E. D.** Cerebral compression, 573.
- Fisher, E. D.** A new hemorrhoid, 7.
- Fitz, E. W.** A case of hydrocephalus, 17.
- Fitz, H. E.** Henry Jacob Bigelow, M.D., 511; perforating gastric ulcer, circumscribed peritonitis, death on the fifteenth day, 583, 585.
- Folsom, C. F.** Disorders of sleep, insomnia, 2, 29; a case of hydrocephalus, 367.
- Food.** The popular science of economic dietetics, 139; national measures for the prevention of food adulteration, 139; bill to prevent food adulteration, 141; food, drugs and their adulterations, Davenport, B. F., 180; the diet of hot weather, 187.
- Ford, W. C.** Quantitative amperage in the treatment of fibroid tumors by electricity, 377.
- Fordyce, J. A.** Peripheral neuritis of syphilitic origin, 39.
- Forsier, E. J.** Cases of epithelial cancer in a negro, 53; mucus-

- rooms and mushroom-poisoning, 267; the study of mushrooms, 334; the agaricus rodmanii not a poisonous mushroom, 454.
- Fourth of July.** The surgical Fourth, 44.
- Frostbite.** Colle's fracture with especial reference to treatment, Huse, R. C., 77; the management of fractured limbs, von Denshoff, E., 541.
- Frankel.** Hypnotal, 531.
- Freer.** A. Influence of syphilis in English country practice, 234.
- Freud, S.** Consumption in Massachusetts, 340.
- Froitzky.** Stomach washing in very young children, 453.
- Frost, C. P.** Potomac, 157.
- Furunculosis.** The treatment of furunculosis, Hofrat, 578.
- Gall-bladder.** Surgery of the gall-bladder, Ricketts, E., 569.
- Gardner.** The local and general treatment of gangrenous wounds and diseases, 545.
- Garcean, E.** Appendicitis, operation, 438.
- Gastrostomy.** A case of gastrostomy, Gay, G. W., 221, 227.
- Gay, G. W.** A case of gastrostomy, 221, 227; appendicitis, 438.
- Gemmell, J. G.** Syphilis in gynaecology, 239; report of progress in gynaecology, Davenport, F. H., 153; unicocular papillomatous cysts of the left ovary, Russell, W., 156; ninety cases of dysmenorrhea and sterility treated by rapid dilatation of the cervical canal, Towner, J. C., 157; the diagnosis of syphilis in gynaecologists and obstetricians, Naidoo, T. M., 158; a case of vaginal hysterectomy, Davenport, F. H., 202, 203; a case of calcareous fibro-myoma of the uterus, Ingalls, W., 201, 204; a case of vaginal hysterectomy for cancer, recovery, 201, 202; question of amputation in the treatment of fibroid tumors, 204; discussion on the diagnosis of syphilis in gynaecology, Cabot, A. T., 205; treatment of uterine fibro-myoma by abdominal hysterectomy, Irish, J. C., 203; a plea for conservatism in minor gynaecology, 203; discussion on the question of amputation in the treatment of fibroid tumors by electricity, 207; vaginal fixation of the uterus after abdominal hysterectomy, 208; removal of a mechanical obstruction in disease of the uterus, Hubert, G., 418; is the mortality after gynaecological operations affected by climatic influences? Cox, H. C., 421; drainage after laparotomy, Ashby, T. A., 422; drainage after laparotomy, Dudley, A. P., 422; two cases of hydrocephalus, Chaylock, J. R., 423; removal of a rectal polypoid tumor by rectal enucleation involving the sphincter, 424; by the flap-splitting method, Banks, H. T., 423; new method of treatment for retro displacements of the uterus with adhesions, Dudley, A. P., 468; sterility 477; how shall we treat our cases of pelvic inflammation, Huse, R. C., 478; a new method of the treatment, Wilkins, J. T., 488; a report on the treatment of varicocele, Lydon, G. F., 492; hydrocele in children, with a report of cases, Lovett, R. W., 504, 502.
- Gibbes, H.** Hyaline-fibroid ovarian disease, 129; is the unity of phimosis an important fact? An important consideration in regard to the cause of the disease, 130; association, 130.
- Gibbes, H., and Shuryl, E. L.** Tubercle bacilli, 487.
- Gibler, F.** Sensations produced by the anti-hydrophobic Pasteur inoculations, as described by inoculated subjects, 184.
- Girard.** The causes of death in American girls and the importance of female hygiene, Engelman, J., 541.
- Gluck, T.** Antiseptic cement for promoting bone union, 235.
- Goggans, J. A.** The surgical treatment of empyema, 579.
- Gonorrhoea.** Some points in the treatment of gonorrhoea, Allen, G. W., 121, 132; treatment of gonorrhoea, 532.
- Gordon, J. C.** Report on primary prostatic obstruction in elderly men, its nature, diagnosis and treatment, 471.
- Graham, H.** Paraffo-stearine, a substitute for starch, plaster of Paris, and such materials, for bandages and splints, 602.
- Graham, J., and Clunie, C. P. B.** A case of hydatid tumor of the brain, with a report of the treatment, 284.
- Grand army meeting,** 161.
- Gray, L. C.** Astasia and abasia, 570.
- Green, C. M.** The influenza epidemic as observed at the Boston Lying-in Hospital, 53; report on obstetrics, 130.
- Green, J. A.** Acute rheumatism after potassium iodide, 21.
- Haeckel.** Phosphorus necrosis, 500.
- Hemophilus.** A case of hemophilus as observed at the first menstrual period, Townsend, C. W., 516, 525; menorrhagia in a patient afflicted with hemophilus, Vickery, H. F., 520, 525; a case of hemophilus observed at the first menstrual period, Tinkham, G. W., 525.
- Hall, J. N.** A case of homicide in which the location of the powder brand assisted in establishing the innocence of the accused, 152.
- Haller, J. E.** Modern physical deterioration and some remedial suggestions, 100.
- Hammond, G. M.** The pathological findings in Dr. W. A. Hammond's case of atethosis, 63.
- Hanks, H. T.** A report of my recent experience in restoring lacerations involving the sphincter and by the flap-splitting operation, 443.
- Hanson, G. C.** Transient amblyopia with bi-temporal hemianopsia in a case of malarial cachexia, 136; a new operation for symbiapharon, 161.
- Harriman, A. H.** Combined intra and extra twin pregnancy, 156.
- Hartington, H.** Epidemic influenza and insanity, 126.
- Hastings, F. B.** The value of "primary anesthesia" in minor surgical operations, 434, 441.
- Hartford.** Old physicians of Hartford, 333.
- Heart failure.** Whittier, E. N., 222, 227.
- Help and hinderance to medical progress.** Hollister, J. H., 418.
- Hemophilus.** A true hemophilic, Fitch, C. W., 571.
- Henter.** A contribution to the pathology of the solitary tubercle of the spinal cord, 89.
- Hilland, T.** Medical men, 158.
- Hills, J. B.** Report on medical chemistry, 6.
- Hicks.** A case of compound fracture of the hip, with recovery, Perkins, J. W., 362.
- Hofrat.** The treatment of arachnælosis, 578.
- Holden, K.** Wire-loop curette for removing new adenoid growth from the pharynx, 418.
- Hollister, J. H.** Help and hinderance to medical progress, 418.
- Holt, L. E., and VanGieson, L.** Case of spina bifida with suppurative meningitis and epidymitis of bacterial origin, 572.
- Homans, J.** A case of vaginal hysterectomy for cancer, recovery, 201, 202; case of carcinoma of the tonsil, removed by external incision, 201; case of carcinoma of the tonsil, removed by external incision, 201.
- Homans, J. Snd.** Observations on a case of periphlebitis, 61, 81.
- Hooper, F. H.** Report on laryngology and rhinology, 413.
- Hospitals.** The Boston City Hospital, Blaize, C. J.; the New York Floating Hospital, 211; Boston Children's Hospital, 66.
- Hoyle, L.** The removal of a bullet from the ear with the assistance of the galvanic-cautery, 111; legislation for the prevention of blindness, 159.
- Huibert, G.** Mechanical obstruction in disease of the uterus, 418.
- Huse, R. C.** Colley's fracture, with especial reference to treatment, 77.
- Hydrophobia.** M. Pasteur and hydrophobia, Dolan, T. M., 177; sensations produced by the anti-hydrophobic Pasteur inoculations, as described by inoculated subjects, Gilber, F., 184; a case of hydrophobia, Folsom, C. F., 367; rabies, Ernst, H. C., 368; a hydrophobic scare, Spring, C. W., 369.
- Hygiene and Health Boards of Health.** The Berlin water and sewage works, Virchow, K., 189; the functions of State boards of health, 208; Colorado as a health resort, Atkins, E. C., 336; international congress of hygiene and demography, 454; hygiene in the public schools, Chamberlain, H. S., 372; the relative value of pharmacocauterization and thermotherapy, 476.
- Hypnotism.** Some conservative views of hypnotism, 21; a grand exhibition of hypnotism, 46; blistering by hypnotic suggestion, Rybalkin, I. V., 333; hypnotism in its relation to surgery, Lampman, E., 468; hypnotism, Schmid, E., 476.
- Hysteria.** Some extra-medical manifestations of hysteria, Washington, C. F., 393.
- Immigrants.** Medical inspection of immigrants by consular physicians, 11.
- India.** Early marriages in India, 357.
- Inflammation.** Recent views as to inflammation, 67; the pathology of inflammation, 37.
- Influenza.** Influenza in Massachusetts, Shattuck, G. B., 25, 49, 73; the influenza epidemic as observed at the Boston Lying-in Hospital, Green, C. M., 55, 59; epidemic influenza and insanity, Harrington, H., 56; influenza through the eyes, 56; report of the Boston City Hospital, Buckingham, C. E., 343, 348.
- Ingalls, E. F.** Supplemental report on cartilaginous tumors of the larynx and warty growths in the nose, 35; unilateral paralysis of the lateral crico arytenoid muscle, 36.
- Ingalls, W.** A case of calcareous fibro-myoma of the uterus, 201, 202.
- Inheritance of disease, 159.**
- Insomnia.** Disorders of sleep, insomnia, Folsom, C. F., 2, 29.
- Instruments and Apparatus.** An instrument for removing glaucomatous cataracts, the angustator, Root, C. O., 12; wire-loop curette for removing adenoid tissue, growth from the nose, 122; Holden, E., 12; the anastomotic percurser, Seaman, L. L., 63; extractors for litholapaxy, Newell, O. K., 133; another needle forceps, Burrage, W. L., 271; a new bed for use in hip disease, Phelps, A. M., 274; a simple female catheter, Kunkel, H. O., 422; Professor Jackson's apparatus for the removal of polypoid structures, an apparatus for starch, plaster-of-Paris, and such materials, for bandages and splints, Graham, H., 602.
- International congress of hygiene and demography, 454.**
- Irish, J. C.** Treatment of uterine fibro-myoma by abdominal hysterectomy, a simple procedure, usually synchronous amputation of the lower extremities, with recovery, 616.
- Irwin, F.** A large surgical cyst of the kidney, 278.
- Italy.** Letter from Italy, 500, 552.
- Jackson, F. L.** Adenoid growths in the nasopharynx, result of their removal in seventy cases of middle ear disease, 297, 301.
- Jackson, G. T.** Electrolysis in the treatment of lupus vulgaris, 255.
- James, J. B.** Atropia in the treatment of enuresis, 261.
- Jay, G.** Small tumor of the upper jaw, Richardson, M. H., 325.
- Jewett, G.** A case of ruptured tubal pregnancy, 331; the comparative value of bismuth and bichloride of mercury as surgical antisepsics, 443.
- Johnstone, A. W.** Diagnosis, pathology and treatment of extra-uterine pregnancy, 336.
- Joints.** High temperature in chronic joint disease, Lovett, R. W., 27; chronic synovitis of knee, Ketch, S., 273; suppurative inflammation of the knee-joint treated by drainage through the popliteal space, Richardson, M. H., 277.
- Judson, A. H.** Hematoma of the sternocleido mastoid muscle, 74; ankle-joint disease, 74.
- Jurisdiction.** A case of homicide in which the location of the powder brand assisted in establishing the innocence of the accused, Hall, J. N., 152; two medico-legal decisions, 293.
- Karewaki.** The diagnosis and treatment of cysts of the pancreas, 600.
- Kay, H. A.** Continuation of the discussion on ectopic pregnancy, 375; cephalhematoma, 421.
- Ketch, S.** Rheumatic arthritis of knee, 273; posterior rachitic curvature of the spine, 328.
- King, W. P.** Wiring the separated symphysis pubis, supplemented by a new clip, 328.
- Kisch, H.** Treatment of obesity, 233.
- Klotz, H. G.** Notes on pilocarpine in dermatology, 255.
- Knee.** Excision of the knee for angular ankylosis, report of four cases, Lovett, R. W., 178.
- Knight, G.** A case of myo-sarcoma of the right nasal fossa, with unusual clinical history, 34.
- Knoff.** Pericarditis in childhood, 380.
- Koch.** Koch's cure for consumption n. 476; Koch's treatment for tuberculosis, 497, 571, 598; Professor Koch's subcutaneous syringe, 571; Koch's lymph, 599; inoculations for pulmonary tuberculosis, Boldt, H. J., 597.
- Kollock, C. W.** A form of xerosis, 169; two cases of glaucoma, 160.

- Lamphier, E. H.** Hypnotism in its relation to surgery, 446.
- Langdon, W. F.** Tendonotomy to increase the mobility and power of the musician's finger, 118.

- Langmaid, S. W.** Hoarseness and loss of voice caused by wrong vocal method, 36.
- Larototomy.** Two cases of larototomy for tubercular peritonitis, 191; another, with drainage after larototomy, Ashby, T. A., 422; drainage after larototomy, Dudson, A. P., 422; larototomy for intra-pelvic pain, Ashby, T. A., 444; larototomy under cocaine, 191.
- Larynx.** Report on laryngology and rhinology, Hooper, F. H., 413.
- Law, G. E.** The treatment of pseudo-membranous laryngitis by mercury fumigation, 225.
- Lee, R.** The nervous and muscular elements in the causation of idiopathic curvature, 327.
- Leprosy.** A case of leprosy, McCollom, J. H., 350; leprosy in Venezuela, 432.
- Lewis, H. T.** A case of ruptured intestine, 222.
- Liber.** A two hundred thousand dollar Liber suit, 282.
- Lichen.** Clinical notes on lichen planus, Bulky, L. D., 405.
- Lippincott, J. A.** Mastoiditis interna purulenta erysipelas, 112; new tests for binocular vision, 137.
- Litholabaxyl.** Evacuators for litholabaxyl, Newell, O. K., 133.
- Liver.** Cancer of liver, Stedman, C. E., 325.
- Lowe, I. N.** Coffee, 418.
- Loveitt, R. W.** Excision of the knee for angular ankylosis, report of four cases, 178; high temperature in chronic joint disease, 133; the treatment of abscesses without drainage, with report of cases, 273; strobiloma of the sacrum, 327; lateral deviation of the spinal column in Pott's disease, 304; malignant cerebral edema, 409; hydrocele in children, with a report of cases, 584, 592.
- Lydon, G. F.** A review of the treatment of varicocle, 569.
- Lyman, G. H.** Some aspects of our medical service in the War of Independence, 140, 169.
- MacCoy, A. W.** A case of fibro-myomatous tumor taken from the naso-pharynx of a child six years of age, 13.
- Mackenzie, J. N.** Annual address before the American Laryngological Association, 10; a suggestion concerning the intimate relationship between buco-nasal disease and certain obscure nervous conditions of the head and neck, 10.
- Mackenzie, S.** African sleeping sickness, 601.
- Madden, T. M.** Ovarian hernia, their causes, symptoms and treatment, 190; the treatment of cystitis in women, 211.
- Manley, T. H.** Coccidi analgesic its extended application in general practice, with hypodermic syringes, 455.
- Materia Medica and Therapeutics.** Recent speculations as to the nature of cancer, the electrolytic treatment of cancer, 18; iodide of sodium and iodide of potassium, Coggins, D., 47; cases of cystitis treated with salol, Abbot, S. L., 57; r-marks on therapeutic applications to the skin, 17; a new antiseptic for the eyes and nose at Berlin, 234; the treatment of pseudo-membranous laryngitis by mercurial fumigation, Law, G. E., 235; anti-septic cement for promoting bony union, 235; electrolysis in the treatment of lupus vulgaris, Jackson, G. T., 235; aristo, Allen, C. W., 235; non-pitting cellulose dermatitis, King, H. G., 238; the treatment of dermatological cases by sulphur water at Rindfield Springs, Ransom, C. C., 235; antisepsis and asepsis in surgery, 236; atropia in the treatment of enuresis, James, J. B., 261; the true position of electricity as a therapeutic agent in medicine, Prince, M., 263; the use of the hypodermic syringe for the treatment of malaria, Watson, G. L., 282; chlorate of potassium as a preventive of intra-uterine death, Chadwick, J. R., 284; some new clinical experiments with diuretin, 426; the comparative value of biniodine and binichloride of mercury as surgical antiseptics, Jewett, C., 443; the use of podemic use of arsenic, Moyes, H. H., 447; cocaine analgesic in the treatment of acute appendicitis, surgery when hygienically employed, Manley, T. H., 458; calomel plaster for syphilis, Quiniquand, 476; strichnine as an antitussive vaccine, Peyraud, 478; the continuous inhalation of oxygen in pneumonia otherwise fatal, and other diseases, Blodgett, J. H., 481; the use of oxygen in therapy, Hinman, H. H., 480, 481; hypmal, Franklin, 531; war antiseptic dressing in injuries of the hand, Nicolson, W. P., 568; soda, some new methods of use in surgery, Baxter, G. A., 569; peroxide of hydrogen, 579.
- Maurry, R. B.** How shall we treat our cases of pelvic inflammation? 550.
- McCollom, J. H.** A case of leprosy, 350.
- McKinley Bill.** Changes in the tariff on drugs, 476.
- McMurtry, L. S.** The application of antiseptic methods in midwifery practice, 448; inflammation in and about the head of the colon, 544.
- Medical examiner vs. the coroner, 500.**
- Medical men, Hillard, T.** 158.
- Medical register for New England, 577.**
- Microscopy.** Hardening of sections of the spinal cord by electricity, 500.
- Milkhouse, E. L.** Case of a foreign body remaining in the eye about twenty years, followed by abscess in the scleral wall, opened and removed, 136; complete paralysis of the lateral movements of both eyes, ability to converge remaining intact, 137.
- Mintz, T.** The immunity of certain diseases, 112; epidemic influenza and meningitis, 112; the prognosis of the ocular symptoms found in the third stage of general paralysis of the insane, Oliver, C. A., 161; the care of the insane in local institutions, Moulton, A. B., 166.
- Minor.** Hardening of sections of the spinal cord by electricity, 476.
- Mixter, S. J.** The indications for trephining in epilepsy, 593.
- Minot, C. S.** On the fate of the human decidua reflexa, 561.
- Minot, F.** Sudden death probably from edema of the glottis, 538, 540.
- Mitchell, S. W.** Double consciousness, 42.
- Mitchell, S. W., and Burr, C. W.** Unusual forms of chorea, possibly of spinal origin, 41.
- Mittendorf, F. W.** Embolism of the upper branch of the retinal artery, with normal vision, 160.
- Mixter, S. J.** Stricture of the oesophagus, its treatment by intubation, 36; man with stricture of the oesophagus, its treatment by Symond's method of permanent tube, with cases, 385.
- Mollenhauer, R.** On the germ of a communicable disease derived from a dog, alleged to have died of rabies, which retains rabid characters, 90.
- Monks, G. H.** A new method for the treatment of injuries to the shoulder, 183; a case of enlarged subcutaneous bursa in front of the tubercle of the tibia, 591, 592; enormous hypertrophy of the nose, 592.
- Morris, W. F.** Brain tumor, with interesting eye-symptoms, 135.
- Morrison, W. A.** Address before the American Dermatological Association, 202.
- Mortality vs. immortality, 547.**
- Morton, T. G.** Method of dealing with club-foot, 327.
- Moulton, A. B.** The care of the insane in local institutions.
- Moyer, H. H.** The hyperacute use of arsenic, 447.
- Mumpa.** Mumps and inflammation of the male penis, 16.
- Mumps.** Mumps and inflammation of the lacrimal gland, Dufour, 357; mumps, Bordas, 477.
- Murdock, R.** Tortion of arteries as a means for the arrest of hemorrhage, 426.
- Muscarine.** Diffuse calcification of the muscular system in a case of fracture, Chase, W. D., 158.
- Mushrooms and mushroom-poisoning.** Forster, E. J., 267; the study of mushrooms, Forster, E. J., 334; the agaricus rodmani not a poisonous mushroom, Forster, E. J., 434; the study of mushrooms, Forster, J. A., Jr., 434.
- Musicians.** Tenotomy to increase the mobility and power of the musician's finger, Langdon, F. W., 118.
- Myers, T. H.** The prognosis of pressure paralysis, 328; the treatment of ankle-joint and tarsal disease, 617.
- Nerve palsies.** A case of palsies of the crico-arytenoid muscle, Ingalls, E. F., 36; a case of unilateral palsy of the larynx, the result of an attack of bulbar disease, with unusual symptoms, Bosworth, F., 36; peripheral neuritis of syphilitic origin, cordyce, A. A., 39; peripheral form of chorea, possibly of spinal origin, St. John, S. W., and Burd, C. A., 41; discorrhaphy, Minot, C. W., 42; chronic softening of the cord, senile paraplegia, Dana, C. L., 42; a case in which cerebral localization was illustrated by the effect of mental impression, Smith, A. H., 45; traumatic neuro-psychoses, Walton, G. L., 60; a case of complete paraplegia cured by removal of a tumor, a case of hemiplegia associated with a tumor associated with nuclear cranial palsies and with muscular atrophies, Peterson, F. E., 61; multiple neuritis, or beri-beri, among seamen, Putnam, J. J., 62; on cases of postero-lateral sclerosis, with special reference to the pathology of the disease, Putnam, J. J., 62; the diagnosis of peripheral neuritis, a case of bilateral neuritis, Hammond, G. M., 63; on ingraevaceous species, Dana, C. L., 63; pons lesions in their relations to associated eye movement palsy, Spitzka, 89; a contribution to the pathology of the solitary tubercle of the spinal cord, Hunter, 89; demonstration of some special anomalies in the peripheral nerves, with special reference to those associated with nuclear cranial palsies and with muscular atrophies, Wilder, B. J., 89; tumor of the quasi-tigeminal region with special reference to ocular symptoms, Sachs, H., 89; cataract, Sachs, H., 89; on the germ of a communicable disease derived from a dog, alleged to have died of rabies, which retains rabid characters, Mixter, S. J., 90; a case in which a sudden attack of cerebral hemorrhage arrested the tremor on the hemiplegic side, Sinker, W., 91; remarks on therapeutics as applied to nervous disorders, Birdsell, W. K., 91; M. Pasteur and hydrocephalus, Dolan, T. M., 117; brain tumor with interesting eye-symptoms, Morris, W. F., 129; the prognosis of pressure paralysis, 135; the eye-symptoms of a tumor verified at autopsy, Oliver, C. A., 185; an analysis of the ocular symptoms found in the third stage of general paralysis of the insane, Oliver, C. A., 186; some extra-medical manifestations of hysteria, Washington, C. F., 186; Erichsen's disease, a form of peripheral neuritis, with nerve fiber stains, 217; craniectomies for microcephalic craniostenosis, Wenout, E. C., 208; tumour of polyneuritis, probably analogous to or identical with beri-beri, occurring in seafaring men in Northern latitudes, Putnam, J. J., 244; a case of hydatid tumor of the brain, removal, recovery, Gratz, 244; a case of peripheral neuritis, with nerve fiber stains, 244; Sayre, H. B., 244; a case characterized by shock and sudores paroxysmata, Dana, I. T., 285; the treatment of deformities of spastic paralysis, Bradford, E. H., 303; a case of considerable cerebral hemorrhage without symptoms, Shattuck, G. B., 324; the prognosis of pressure paralysis, Myers, H. H., 324; the nerve fiber stains, 324; fatal convulsions in a man in whom ataxia was the principal symptom (pseudo tabs), Walton, G. L., 411; a case of multiple neuritis due to arsenic, Cutler, E. G., 463, 465; a case of pseudo-muscular hypertension in an adult, Cutler, E. G., 465; discussions on intra-cranial and spinal surgery, with special reference to the nervous system, its indications and feasibility, Sennar, E. C., 608.
- Newell, O. K.** Evacuators for litholabaxyl, 133; value of cystoscopy in the diagnosis of surgical diseases of the kidney, 591.
- New Jersey.** The regulation of the practice of medicine in New Jersey, 34.
- Newton, W. P.** Wet antiseptic dressings in injuries of the hand, 524.
- Noises.** Unnecessary noise an avoidable evil in a city, Buckingham, E. M., 430.
- Norman, S.** Treatment of organic stricture of the male urethra, 446.
- Norris, W. F.** Foreign body in the orbit, 137.
- Nose.** Congenital deformity of the nose, Bradford, F. H., 586; enormous hypertrophy of the nose, Monks, G. H., 592.
- Noyes, H. H.** Treating the patient with amphetamine and its results, 138.
- Obstetrics.** Treatment of obesity, Kinch, H., 228.
- Obstetrics.** Report on obstetrics, Green, U. M., 130.
- Edema.** Acute circumscribed edema, Lovett, R. W., 469.
- Oesophagus.** Stricture of the oesophagus, its treatment by intubation, Mixter, S. J., 326; malignant stricture of the oesophagus, its treatment by Symond's method of permanent tube, with cases, Mixter, S. J., 383.

INDEX TO VOLUME CXIII.

- Oliver, C. A.** History of a case of intracranial neoplasm, with localizing eye-symptoms, position of tumor verified at autopsy, 135; an account of the ocular symptoms found in the third stage of general paroxysm of the insane, 361.
- Optium.** Breaking the opium habit, Ball, 477.
- Orton, J. G.** Address before New York State Medical Association, 468.
- Orthopaxy.** The treatment of lateral curvature, Bradford, E. H., 256; rachitic posterior curvature of tibia, Townsend, W. R., 275; address before the American Orthopedic Association, Willard, DeF., 303; the treatment of deformities of spastic paralysis, Bradford, E. H., 303; amputation as an orthopedic measure, Vanes, A. M., 303; method of finding the exact point of fracture, Taylor, H. L., 304; nerves and muscular elements in the causation of idiopathic curvature, Lee, B., 377; the strength of the back muscles of one thousand one hundred and forty-one of the school-girls of Boston, Scudder, C. L., 327; the etiology of lateral curvatures, Lovett, R. W., 327; the treatment of club-foot, Moore, C. L., 327; the treatment of lateral curvature, Bradford, E. H., 327; the treatment of lateral curvature, Lovett, R. W., 327; a report of sixty-two cases of hip disease observed in the practice of H. O. Thomas of Liverpool, Ridlon, J., 327; diseases of the eye associated with spinal curvature, Young, J., 327; treatment of rachitis by diet, Koch, A., 327; severe deviation of the spinal column in Pott's disease, Lovett, R. W., 328, 345; a ready method for counter-extension of the knee, Taylor, H. L., 361; a determination of the muscular strength of growing girls and its relation to the etiology, treatment and prognosis of lateral curvature of the spine, Scudder, C. L., 361; an outline of the history of orthopedic surgery, Bradford, E. H., and Lovett, R. W., 429, 461.
- Orvanomas.** The federal district in the Republic of Mexico, as a suitable residence for persons predisposed to tuberculosis, and for the relief of pulmonary consumption, 619.
- Otitis.** The removal of the lobule of the prostate, with complete restoration of the functions of the bladder, 15.
- Oxaluria and nervous states,** 463.
- Oxygen.** The continuous inhalation of oxygen in cases of pneumonia otherwise fatal, and in other diseases, Blodgett, A. N., 481, 493.
- Patterson, J. A. Jr.** The study of mushrooms, 351.
- Pawson.** The diagnosis and treatment of cysts of the pancreas, Karczewski, 600.
- Pancreatitis.** A case of acute pancreatitis, 36.
- Paris.** Letters from Paris, 22, 381.
- Pauwels.** The cause of hydrocephalus, Dolan, T. M., 117; New York Pasteur Institute, 405.
- Pavy, F. W.** The treatment of diabetes, 236.
- Pean, Dr.** 22.
- Pelvis.** The motive and method of pelvic surgery, Price, J., 543.
- Peritonitis.** Two cases of laparotomy for tubercular peritonitis, Wiesner, L., 211; the treatment of general septic peritonitis, Robinson, W. L., 546.
- Perityphlitis.** Observations on a case of perityphlitis, Homans, J., 2nd, 81, 84.
- Perkins, J. W.** A case of compound dislocation of the hip, with recovery, 362.
- Peroxide of hydrogen,** 579.
- Petersen.** Curetting the soft chancre, 476.
- Peterson, F.** A case of locomotor ataxia associated with nuclear cranial nerve palsies, and with muscular atrophies, 61.
- Peppermint.** Strychnine as an antitussive vaccine, 478.
- Pfeiffer, O. J.** The medical department of the Union Pacific Railway, 405.
- Pharmacy.** The relative value of pharmaceutical and hygienic therapeutics, 472.
- Pharynx.** Eight cases of large pulsating arteries on the posterior wall of the pharynx, Farlow, J. W., 6; cases of crysiphiles of the pharynx, Schenckard, K. G., 357.
- Phelps, A. M.** A new bed for use in hip disease, 274.
- Phosphorus necrosis,** Hinman, 569.
- Phthisis.** Professor Flint's doctrine of the self-limitation of phthisis, Porter, W. H.; consumption in Massachusetts, Stetson, G. R., 454; Koch's cure for consumption, 474; is the unity of phthisis an established fact? an important consideration in regard to the cure of the disease by inoculation, Gibbs, H., 608.
- Phined, F. Dr.** Below the nose, the introduction of ether, 554.
- Poisoning.** Poisoning in the Boulay presidency, 234; mushrooms and mushroom-poisoning, Forster, E. J., 267, 334; fatal case of lead poisoning in which ataxia was the principal symptom (pseudo-tubes), Walton, G. L., 411.
- Polyomyelitis.** Some cases of mastoid cell disease with a fistulous opening which recovered without the use of the drill or chisel, 112.
- Pooler, T. H.** Removal of a large exostosis of the orbit with preservation of the eye, 136; operation for ectropion of the lower lid by the sliding-flap method, 136.
- Porter, C. B.** Operation at the shoulder-joint for sarcoma, 181; two cases of relapsing appendicitis, operation between attacks, removal of appendix, recovery, 611.
- Porter, W.** Professor Flint's doctrine of the self-limitation of phthisis, 418.
- Post, A.** Case of coccydynia, removal of coccyx, recovery, 300; suprapubic lithotomy in a boy of twelve, 382.
- Porter, S. O. L.** A road-help for the country doctor, 551.
- Porter, T.** Certainty in the diagnosis of tuberculosis, 446.
- Potter, C. A.** Non-union of fractured radius, 616.
- Pregnancy, Affection connected with.** A case of greatly prolonged pregnancy, Wilson, R. C., 326; anæsthesia, Gossage, C. M., 130; combined intra and extra twin pregnancy, Harriman, A. H., 136; posthumous labor, 165; some new advice to those who would practice antiseptic midwifery, 166; after-treatment of obstetric cases, 166; a case of uterine prolapse, 167; a case of extra-uterine pregnancy, Jamieson, A. W., 338; a case of tubal pregnancy, Jewett, C., 351; ectopic pregnancy, Baidy, J. M., 351; ectopic pregnancy, Kelly, H. A., 355; early marriages in India, 357; obstetrical work in a cottage hospital, Colt, H., 386; injuries to the uterus during labor, Skene, A. J. C., 393; two unusual obstetric cases, 393; Vickery, J. C., 393; two cases of tumor coincident with pregnancy, Ballou, H. C., 423; two cases of tumors coincident with pregnancy, Charkwick, J. R., 424; chloride of potassium as a preventive of intra-uterine death, Chadwick, J. R., 424; pregnancy after the removal of both ovaries, Robertson, J. A., 425; measurements of the uterus in a child-bed, Richardson, W. L., and Sinclair, A. D., 444; wiring the separated symphysis pubis, supplemented by a novel pelvic clamp, King, W. P., 446; two cases of tubal pregnancy, Walker, E., 447; the application of antiseptic methods in midwifery practice, McMichael, J. C., 448; other cases, 448; two cases of pregnancy complicated with tumors, Chadwick, J. R., 452; indications for treatment in ectopic pregnancy, Reed, C. A. L., 454.
- Price, J.** The motive and method of pelvic surgery, 543.
- Prince, M.** The true position of electricity as a therapeutic agency in medicine, 313.
- Pruritus.** Observations on pruritus, clinical and pathological, Taylor, R. W., 233.
- Purritus.** A clinical study of puritus hemialis, winter itch, frost itch, etc., Corlett, W. T., 233; a study on pruritus, Bronson, E. B., 233.
- Punomines.** Frost, C. P., 157.
- Pubes.** Wiring the separated symphysis pubis, supplemented by a novel pelvic clamp, King, W. P., 446.
- Putnam, J. J.** Multiple neuritis or beri-beri among seamen, 69; on cases of tubercular sclerosis, with special reference to the pathology of the disease, 62; a form of polyneuritis, probably analogous to or identical with beri-beri, occurring in seafaring men in Northern latitudes, 244.
- Queen Bess.** The reign of good Queen Bess, Richardson, B. W., 308.
- Quinney.** The Quinney diet, 476.
- Railway.** Railway hygiene, Conn, G. P., 155; the medical department of the Union Pacific Railway, Pfeiffer, O. J., 405.
- Randall, B. A.** The Sharpnell perforation, 112; can hypermetropia be healthfully overcome, 137.
- Ranson, G.** A new treatment of dermatological cases by sulphur water at Riechert Springe, 255.
- Rarieties.** Clinical study of rarities or of common diseases, 282.
- Recent Progress.** Report on medical chemistry, Hills, W. B.; diseases of children, Rotch, T. J., 103, 187, 614; bacteriology, Green, C. M., 103; pulmonary tuberculosis, Roosevelt, F. D., 153; the development of the tubercle bacillus, 154; septic peritonitis, Wiesner, L., 211; dysentery, Davenport, B. F., 180; surgery, Burrell, H. L., and Cushing, H. W., 319; anatomy, Dwight, T., 391; laryngology and rhinology, Hooper, F. H., 413; orthopedic surgery, Bradford, E. H., and Lovett, R. W., 439, 461; therapeutics, Williams, F. H., 490, 516; ophthalmology, Standish, M., 533; report on progress in dermatology, Bowen, J. T., 562, 589; report on recent progress in medicine, 598.
- Reed, C. A. L.** Indications for operation in ectopic gestation, 545.
- Respiratory System.** A suggestion concerning the intimate relationship between bulbo-nuclear disease and certain obscure neurotic conditions of the upper air-passages, MacKenzie, J. N., 19; look beyond the nose, Cohen, S. S., 11; an instrument for removing glandular hypertrophies from the tongue, Roe, J. O., 12; wire-loop curette for removing adenomatous new growth from the pharynx, Homans, E., 12; a new operation for removing a growth from the nose, Asch, M. J., 12; a case of fibro-myxomatous tumor taken from the nasal-pharynx of a child six years of age, MacKay, A. W., 13; acute edema glottidis after potassium iodide, Groenow, 21; case of fibro-sarcoma of the right nasal fossa, with unusual clinical features, a right-sided tumor of the nasal-pharynx, a preliminary report on the development and variability, Swain, H. L., 33; supplemental report on cartilaginous tumor of the larynx and warty growths in the nose, Ingalls, E. F., 35; myxoma of the epiglottis, Van der Poel, S. O., 35; hoarseness—a loss of voice due to wrong vocal method, Langmaid, S. W. the well-known cause of tuberculosis, Bunting, J. B., 36; a case of partial paralysis of the crico-arytenoid muscle, Ingalls, E. F., 36; a unilateral paralytic of the larynx, the result of an attack of bu-disease, with unusual symptoms, Bosworth, F., 36; on the diagnosis of intestinal disease, the larynx, Ingalls, E. F., 36; the ascenders, penes, Seman, L., 68; cardiac dyspepsia, 91; the gross anatomy of chronic pulmonary consumption in relation to diagnosis and prognosis, Roosevelt, J. W., 205; paroxysmal pulmonary edema in chronic albuminuria, Bouvier, 211; the treatment of pseudo-membranous laryngitis by mercurial fumigation, 211; on the diagnosis of intestinal disease, Ingalls, E. F., 214; influenza in the out-patient department of the Boston City Hospital, Buckingham, E. M., 343, 348; Professor Flint's doctrine of the self-limitation of phthisis, Porter, W. H., 418; cough, its relation to intra-nasal disease, Thresher, A. B., 419; consumption in Massachusetts, Stetson, G. R., 454; Koch's cure for consumption, 474; the continuous inhalation of oxygen in cases of pneumonia otherwise fatal, and in other diseases, Blodgett, A. N., 481, 493; sudden death, probably from edema of the glottis, Minot, F., 536; the surgical treatment of emphysema, Gossage, C. M., 570; manipulative treatment of chronic neuralgia, 570; congenital deformity of the nose, Bradford, E. H., 588; enormous hypertrophy of the nose, Mouka, G. H., 592; is the unity of phthisis an established fact? an important consideration in regard to the cure of the disease by inoculation, Gibbs, H., 608.
- Rheumatism.** Electricity for rheumatism, 382.
- Rhinoplasty.** A case of rhinoplasty, Cook, G., 226.
- Rice, C. E.** The condition known as chordite tuberosa, 36.
- Riley, J. E.** The nitro-ether test, 157.
- Ridlon, J. A.** Report of sixteen cases of hip disease observed in the practice of Hugh Owen Thomas of Liverpool, 327.
- Richards, H.** Mastoid sclerosis as illustrated by a typical and fatal case, 116.
- Richardson, W. H.** The reign of good Queen Bess, 308; the diaphanus test of death, 332.
- Richardson, M. H.** A successful case of gastrotomy for removal of foreign bodies, 177, 183; suppurative inflammation of the knee-joint treated by drainage through the popliteal space, 277; small tumor of the upper jaw, 325.
- Richardson, W. L. and Sinclair, A. D.** Measurements of the uterine cavity in child-bed, 444.

- Richfield Springs.** The treatment of dermatological cases by sulphur water at Richfield Springs, Ransom, C. C., 255.
- Ricketts, B. M.** Some observations on bone and skin grafting, 523.
- Secretary of the gall-bladder.** 569.
- Hilzer, S. D., and McConnell, E. A.** Cyst of the iris following a penetrating wound at the corneal margin which caused sympathetic neuro-retinitis, 161.
- Road-help for the country doctor.** Potter, S. O. L., 551.
- Roberts, W. O.** Removal of stone from female bladder through the urethra, with notes, 567.
- Robertson, A.** Pregnancy after the removal of both ovaries, 429.
- Robinson, W. L.** The treatment of general septic peritonitis, 546.
- Roe, J. O.** An instrument for removing glandular hypertrophies from the tongue, 12; a case of stricture of the oesophagus from intestinal thickening, 56; a case of stricture of the rectum, 12.
- Roosevelt, J. W.** The gross anatomy of chronic pulmonary consumption in relation to diagnosis and prognosis, 295.
- Rotch, T. M.** Report on diseases of children, 103, 587, 614.
- Russell, W.** Unicular papillomatous cyst of the left ovary, 156.
- Sachs, H.** Tumor of the quidamianus muscle with special reference to ocular symptoms, 89; crux lesions, 90.
- Salol.** Cases of cystitis treated with salol, Abbott, S. L., 57.
- Sayre, R. C.** A case of congenital lock-jaw, 274.
- Schoenlein Aleutus.** The micro-organisms of standing water, 551.
- Schenck.** A case of tetany, 333.
- Schmid, E.** Hypnotism, 470.
- Schools.** Hygiene in the public schools, Chapin, H. S., 472; physical training in the public schools, 544.
- Seidensticker, C. Address.**THE BOSTON CITY HOSPITAL.¹**

BY CLARENCE J. BLAKE, M. D., BOSTON.

FORTY-ONE years ago, in Boston, with a population of one hundred and thirty-six thousand, the principal provision for the house care of the sick poor, other than that to be found in their own homes and in public institutions, was afforded by the Massachusetts General Hospital; the larger part of the out-patient service of the city being shared by it with the Boston Dispensary and, for special cases, the Massachusetts Charitable Eye and Ear Infirmary. At that time, in 1849, an epidemic of cholera made especial call upon the hospital resources of the city, and stimulated the demand for more accommodation of this kind; the project for the establishment of a City Hospital first took shape, was earnestly favored by the principal physicians in the town, one of whom wisely suggested the reservation of city land for that purpose, and there was prospect for speedy realization, but, the cholera subsided, the necessary order passed by the Board of Aldermen was lost in the Common Council and the hospital without its reserved land to build even a hope upon existed only as a purpose in the minds of those of the medical profession who, working among the sick poor, best appreciated the need existing and to come. This purpose found its voice again in 1856, when the medical profession and the officers of charitable institutions, uniting, urged upon the public in various ways and upon the Council of 1857, through the earnest advocacy of the then Mayor, Hon. Alexander H. Rice, the importance of establishing a hospital which should be at the service of the inhabitants and under the control of the government of the city, but the objection made by certain citizens to the use, as was proposed, of the Lying-in Hospital in Springfield Street again blocked the way, and it was not until 1860 that the land at present so fully and usefully occupied was appropriated for that purpose, and in the following year the foundations for the buildings, to consist of a central structure, two wings or pavilions, and in the rear of the centre the necessary boiler and engine rooms and laundry, were begun.

In May, 1864, the hospital was first opened for the reception of patients, one of the pavilions being devoted to medical and the other to surgical cases, the house-officers, resident graduates as they were called, two in each department, dividing the service between them by an imaginary line, running the length of each pavilion from top to bottom, the single rooms in the basements being used as examination and accident rooms and for isolating purposes.

The conditions of that first year's service as necessarily imposed upon the visiting staff were most onerous, a new building, inexperienced house-officers and untrained nurses, a lack of definition of the authority of the staff, which had to insist, in a building still in part in progress of construction and not yet fully in running order, upon the "benefit to the patient" as the primal object of its existence; these made a combination of difficulties met and overcome with a patient persistence which laid the foundation of the present success of the hospital as a medical institution.²

¹ Read at the Annual Meeting of the Boston City Hospital Club, June 10, 1884.

² The visiting and resident staff, 1864:

Visiting physicians. † W. W. Morland, M.D.; Fitch Edw. Oliver,

The first hospital year was of but seven months duration, and within that time there were 475 patients admitted, 129 accident cases received and 271 outpatients treated; in the next year, 1865, there were 1,066 patients admitted, 242 accidents and 1,143 outpatients; in 1875, 3,424 admitted, 756 accidents and 8,732 out-patients; in 1885, 4,031 admitted, 676 accidents and 12,005 out-patients; while, in the year just ended, there were 6,157 patients admitted to the house, 888 accident cases received and 13,605 people treated as out-patients.

A review of the table in the comprehensive and verbal report of the superintendent,³ from which these figures are taken, shows that while the increase in house-patients has proceeded at a fairly steady pace, the number of out-patients was less by 636 than in 1884, eighteen years only after the opening of the outpatient department.

A consideration of the growth of the buildings of the City Hospital during the past twenty-five years will serve to explain this apparent discrepancy. Beginning in 1864 with the central buildings and wings, which had been expected to afford ample provision for at least a decade to come, in 1872, eight years later, the justifiable demand upon the hospital was so great that, in addition to the beds provided for small pox patients in buildings on the water side of Albany street, beds were placed in the private rooms and in every other available spot to the extent of fifty more than the original provision. The dangers of an overcrowded hospital were fully appreciated by the visiting staff, now increased in numbers, and in their report of that year they set forth the need of more ward room for both medical and surgical cases, adequate reception rooms for accident and for lying-in cases, and the substitution of a suitable operating amphitheatre for that which, situated in the dome of the rotunda and necessitating lengthy transportation of patients, had sufficiently demonstrated its unfitness in the surgical experience of the first year. In 1873-74, a medical superintendent having been in the meantime appointed, the overcrowded condition of the hospital was again reported and the especial need of better surgical

accommodation in the out-patient department as well as in the house was urged, and was met by an appropriation (\$190,000), made by the City Council in that year for the "enlargement or extension of the buildings," the result being the addition of two main buildings for medical and surgical cases respectively, two one-story buildings and a kitchen building, the whole giving an increase in house accommodation of eighty-five beds. In the same year the drainage, plumbing and ventilation were thoroughly overhauled, and the single rooms in the basements of the pavilions, half underground, were abandoned as wards, for obvious sanitary reasons.

At the beginning of its second decade, therefore, the hospital had five new buildings, a considerable increase in its accommodations in the house, and a proportionate enlargement of its working staff, there

Those with the dagger (†) prefixed have since died.

³ Twenty-sixth Annual Report, Boston City Hospital.

being ten out-patient surgeons and physicians and thirteen house-officers, five of that number acting as externes.

In 1878 the work of overhauling the old pavilions and correcting the defects in arrangement was fairly completed, and another step had been taken in the development of the hospital upon a scientific basis in the establishment of the training-school for nurses which, in addition to the public benefit afforded by it outside of its own walls, has served to provide efficiently for one of the most important needs in the successful conduct of a hospital.

At the end of the first year there were in the hospital three head-nurses, graduates of the training-school, nine other head-nurses in charge of wards, twenty-seven assistant or pupil nurses and eight others not belonging to the school. The number of graduates the first year of the school was six and in 1889 twenty-eight. The number of nurses employed to-day in the hospital work is seventy-seven.

In 1879 the reservation of additional land was advised; in 1880 the need of a separate building as a home for the increasing staff of nurses was recommended and the ambulance system, improved in previous years, was well established.

At the end of its second decade the hospital, while enlarged, as has been said in its main departments, had only the same accommodations for contagious cases as that provided in 1866, seventeen years before; the population of the city had in the same time increased over fifty per cent., and the nurses, crowded out by the demands for room for patients, were most inadequately lodged, and the out-patient department equally cramped for want of room, now numbered eight services and received over 40,000 visits per annum. In 1886 the house capacity had been increased to 425 beds, and in the annual report for that year it was shown that over 44,000 out-patient visits had been received and treatment given in a building, which was justly stigmatized, because of its want of accommodation, as "a great blemish and the most disagreeable feature of the hospital establishment"; on the other hand, the nurses' home had been in the meantime completed and was giving satisfactory evidence of its usefulness, and the new contagious wards which were completed two years later were projected.⁴

As it stands to-day, the City Hospital has nine large buildings devoted to the accommodation of patients, and additional buildings for administration, cooking, heating, and otherwise providing for the maintenance of the medical service, two out-patient buildings and a nurses' home, it has 480 beds for patients and these are usually full, it has, in addition to its large amphitheatre, smaller operating rooms in connection with wards in certain special departments of its house service;⁵ its new out-patient building is admirably equipped in all respects. There is a visiting and consulting medical and surgical staff, numbering twenty-four members, an out-patient staff of twenty-five, and a staff of house-officers which will be increased after July 1st next, to twenty-two; fifteen internes and seven externes.

While all of this growth has had in view the primal object of such an institution, in the relief of human suffering, that other and equally essential duty of a

⁴ During the past year 210 cases of diphtheria and 88 of scarlatina were treated in these wards.

⁵ The number of surgical operations in 1864 was 464; during the last year, 1,116.

hospital, the furthering of medical education has been kept in mind. In the very first rules and regulations, this function is recognized in the clause setting forth the conditions under which students may be admitted, and the provisions made for this purpose and the opportunities afforded for clinical instruction in the present City Hospital make it, in this respect, the equal of any hospital in this country, so far as I am aware. It has all the material and nearly all the provisions of a great educational institution, and the spirit of progress is shown in the further improvements already in contemplation, which include provision for discharged convalescents, the still more exact isolation of and provision for contagious cases and for the study of such diseases as may come under this head, and the erection of a fireproof building for the preservation of the clinical records, which already make a substantial library of over eight hundred manuscript volumes, containing the detailed records of more than one hundred thousand cases. As a supplementary library the morgue and autopsy room furnish already thirteen volumes of records of autopsies, of which the average during the past winter was sixteen month, in addition to medico-legal examination.

In relation to the use of selected material for instruction, the City Hospital affords, therefore, not only in its large number of house cases⁶ and its valuable records, but also in its new out-patient buildings, where arrangement is made for the accommodation of student as well as patient,⁷ an opportunity which is individually sufficient for a most thorough and complete system of clinical instruction.

Original Articles.

DISORDERS OF SLEEP: INSOMNIA.¹

BY CHAS F. FOLSON, M.D., CO-REFEREE,
Visiting Physician to the Boston City Hospital.

In studying the disorders of sleep I have confined myself to insomnia, partly because of the inherent difficulties and extent of the subject; partly as my material is so crude and undigested as regards the more abstruse phenomena, that I have left them to the wider experience of our referee, who, as Schiller said of Goethe, need only shake the limbs to have the mature fruit of a ripe knowledge fall in abundance. I find that nearly every physiologist has attempted some theory of sleep, without adding materially to our knowledge why or how we sleep, although the result has been to indicate many of the phenomena which occur while we sleep. Duval calls the suspension of cerebral activity in sleep a function of the brain — the passive condition following the active as regularly as an interval of rest succeeds the heartbeats. Lasègue speaks of the appetite for sleep,

¹ A paper read at the meeting of the Association of American Physicians, Washington, May, 1890.

² For purpose of comparison may be mentioned the in-patient service of the following hospitals connected with medical schools: New York Polyclinic, 40 beds; New York Post-Graduate Hospital, 100 beds; New York Eye and Ear, 100 beds; Long Island College Hospital, 150 beds; Jefferson Medical College Hospital, 125 beds; University of Pennsylvania Hospital, 139 beds.

³ The number of out-patients (new cases) treated last year were: medical, 3,133; surgical, 5,825; diseases of eye, 1,642; diseases of ear, 935; diseases of skin, 933; diseases of women, 577; diseases of nervous system, 338; diseases of throat, 644.

which others liken to hunger and thirst. We certainly explain nothing if we say that drowsiness arises from exhaustion of the activity of the brain cells, or, with Landois, that sleep is due to the using up of the potential energy, especially in the central nervous system, making restoration of energy necessary. Nor do we go much farther in speculating on the existence of a sleep-centre in the brain. The chemical theory of Obersteiner and Preyer, that the acid waste-products produced by the activity of the brain finally reach a degree sufficient to arrest it, and thereby cause sleep until their elimination, is only less satisfactory than Pflüger's view, based upon experiments by Pettenkofer and Voit, and the oxygen hypothesis. The lessened amount of blood in the brain during sleep, as shown by the plethysmograph and otherwise, like the slowed pulse and respiration, cannot be held to be an antecedent cause of sleep, and the increased alkalinity of the blood from greater proportionate elimination of carbonic acid naturally explains nothing in that direction.

What happens in the brain when we sleep is described from a psychological point of view by Mercier,² following Huglin Jackson and Herbert Spencer, as follows: The molecules that were shifted into new positions are still oscillating from the shock. Those that were only slightly disturbed are returning to their original positions; those that were profoundly moved are settling in their new places, presenting more stable attitudes to the action of surrounding forces. Regions that perhaps after long repose were disturbed in the day still continue to emit a mild reverberation of their discharge, and the passage of currents at random through the highest regions under the sole influence of irregularities of pressure, and without guidance from external impressions, has its mental counterpart in the phenomena of dreams.

On the pathology or psychology of wakefulness, I have nothing with which I feel justified in taking the time of the Association. Indeed, the subject in general is difficult of concise treatment or scientific arrangement, and analysis of cases proves unsatisfactory. An examination of my records indicates the following causes or conditions of insomnia, each one of which might be easily expanded into an essay by itself:

(1) The perverse habit of sleeplessness, a result of years, perhaps generations, of misuse of body and brain, I hardly need mention; and scarcely more the habits formed to induce sleep, as regards light and darkness, noise or stillness, idiosyncrasies of position, temperature, etc. These people always are amazed to see how much can be done to form the habit of sleep; what fair sleepers they may finally become by the proper kind of training.

(2) Insomnia from external causes, through the various senses, excluding habit, naturally includes the obvious natural sensations of heat, cold, pain, hunger, light, noise, etc.

(3) Excessive intellectual or emotional activity, including strain, excitement—pleasurable or distressing—grief, fear, worry, anxiety, etc., if sufficiently intense or prolonged. Naturally, as elsewhere, excess is only a relative term in different individuals, or in the same individual under different conditions. With the forced overaction of the brain the nervous discharge, as time goes on, requires greater stimulation until such a degree of exhaustion and instability is

produced that any natural function, even rest or sleep, for a time becomes fragmentary, insufficient, or almost impossible.

(4) Of the reflex causes of insomnia, indigestion, gastric or intestinal, is by far the most common, and it may fail to be indicated in any of the usual ways. As in persistent headache, a cause may be discovered only after repeated experiment in withdrawing one article of food after another, until the offending one is found. Genito-urinary and pelvic disorders come next, with unlimited possibilities thereafter.

(5) The traumatic antecedents of insomnia are purely physical, from a sudden fall or blow, for instance; psychical, as in violent mental shock; or both, such as occurs in railroad accidents, etc. In these cases there is evidently a wide difference in the degree of injury to the brain. The impression may be transient and resulting in restoration to healthy function. It may consist, in almost any degree, slight or great, of disarranging, decomposing, decomposing of cerebral molecules and cells, possibly of association-tracts, sometimes resulting, as Westphal held, in minute patches of sclerosis.

(6) The auto-toxic sources of insomnia in acute diseases need only bare mention; in chronic disease, gout, lithæmia, rheumatism, tuberculosis, syphilis, malaria, leukemia, and chronic nephritis, there is a similar cause independent of any cerebral exhaustion or impaired nutrition which may be produced by them. Probably much at least of the sleeplessness from habitual constipation belongs in this category. I have often found persistent wakefulness an early symptom of some general disease, especially acute rheumatism and arterio-sclerosis, many months before an absolute diagnosis became possible.

The habitual excessive use of tea, coffee, tobacco, alcohol, morphia, chloral-hydrate, bromides, cocaine, or other drugs, is a fruitful toxic source of insomnia. Chronic poisoning from arsenic and from lead, perhaps often by leading to vaso-motor disorders, degenerative disease, and arterio-sclerosis, without the usual symptoms, must not be overlooked.

(7) Exhaustion from wasting diseases and enfeebling conditions, pulmonary consumption, anæmia, starving, profuse and repeated hemorrhages, sexual excesses, impaired nutrition of the brain from either deteriorated quality or diminished quantity of its blood-supply.

(8) Of vascular origin, from hepatic disease, producing venous stasis, from cardiac and renal diseases with increased vascular tension, from asthma and hypertrophied or dilated heart, producing cerebral hyperemia, anæmia or venous engorgement, from arterio-sclerosis, especially that of old age. Exaggerated or insufficient blood-supply to the brain, venous stasis, increased vascular tension, may also arise from syphilitic disease of the bloodvessels, or from disorders of digestion or of the portal system, and be as fertile a source of insomnia as the disturbances in the circulation in women at the menopause and other critical periods in life, including puberty, pregnancy, childbirth and lactation. Here also there may be disordered innervation, as well as disturbed vascular tension and, perhaps, nutrition, such as we often see in less degree during menstruation.

(9) *Vaso-motor.*—In that marvel of scientific research and profound medical knowledge, Meynert's *Erkrankungen des Vorderhirns*, the author repeats a statement previously made by him, that the nutrition

²The Nervous System and Brain, p. 374.

and the *Erregbarkeitsverhältnisse* of the brain depend upon its relative weight, as compared with the weight of the heart. The blood-pressure, however, is naturally not governed solely by the heart and cardiac innervation, but by the resistance which the cerebral capillary vessels offer by virtue of their vaso-constrictor nerves, thus bringing in the higher automatic vaso-motor centres of the cortex, which are subject also to psychical influences, and the reflex vaso-motor centres in the pons and medulla as well as the associations-tracts, the reflex vaso-motor centres of the spinal cord acting only coördinately or subordinately.

This field of study is too broad to be entered upon understandingly in the present state of our knowledge. That vaso-motor paresis constitutes an important feature of the prodromal period of diffuse cortical encephalitis, and probably of other organic disease, as well as in the neuritis of lead and arsenic, must, I think, be admitted. The theory that there is a disease which is essentially of the cerebral vaso-motor centres, involving, perhaps, the associations-tracts and the spinal reflex centres, is one in favor of which much can be said, especially where the symptoms appear rather abruptly in people in otherwise good health, without marked emotional or other exhaustive antecedents, and where the least mental or physical effort produces marked cerebral and spinal hyperæmia. How far vaso-dilator nerves act in such cases is a matter of doubt, the transient or more or less persistent anaemia and hyperæmia of the brain and cord being explained by excess of functional activity or inhibition of function in the vaso-motor centres.

(10) The neurasthenic condition, in exalting the direct and reflex excitability of the nervous system, naturally intensifies the usual causes and conditions of insomnia, the unusual sources of insomnia in neurasthenia, in my experience, being astigmatism and hallucinations of sight or hearing. The eye-strain from astigmatism is often in health unnoticed, when in states of debility it produces headache, dizziness, spasmodic muscular action, or wakefulness.

An hallucination of sight occurring a single time is not uncommon in people in reasonably good health. Frequently repeated, such hallucinations are less rare than is supposed without any indications of mental or other disease. Occasionally, like flashes of light, they are precursors of headache. I have observed frequent hallucinations of hearing only once, independent of insanity.

If of distressing nature hallucinations of sight and hearing may be a fruitful source of insomnia. They occur beyond the power of the will of the individual to call them up, although sometimes able, under some conditions, to cause them to disappear. The hallucinations of sight constitute new arrangements of mental impressions which can be more or less clearly recollected, or they form combinations which seem entirely new. Once I have found two sisters subject to them, and once two sisters, a cousin, and a common grandmother — curiously enough, the different members of the families not knowing each other's peculiarities, which, however, were quite different in kind, until I began my investigations. They had thought them uncanny, and had concealed them.

(11) The neuropathic temperament, usually by inherited predisposition, but which may be acquired. In its pronounced form it is closely allied to the well-marked functional diseases of the nervous system, and

at the critical periods of life, may readily develop into them. It is congenital, or due to early interference with the normal development of the brain, to faulty training, and to bad habits of living. It shows itself in infancy and childhood by irregular or disturbed sleep, irritability, apprehension, strange ideas, great sensitiveness to external impressions, disagreeable dreams and visions, romancing, intense feeling, periodic headache, muscular twichings. There are often excessive shyness, introspection and self-consciousness, or extreme self-assertion or conceit. The imitative and imaginative faculties may be quick, the emotions strong, the affections intense or almost absent. The natural feelings easily become disturbed and perverted. The passions are unduly a force in the character, which is commonly said to lack will-power. Self-discipline is a mighty task, and self-control is acquired only with great difficulty. The memory is now and then phenomenal. There is a ready reaction to external circumstances, even to the weather, by which the individuals become easily a little exhilarated or somewhat depressed. They are apt to be self-absorbed, and may be suspicious, or morbidly conscientious. Slight physical ailments, hardly noticed or rapidly recovered from in sound constitutions, leave on them a long or lasting impression. They readily become neurasthenic, hypochondriacal, or nervous invalids, so called, and they break rules or disregard established customs with less cause or provocation than other persons. They lack stability, or have in special directions narrowed limitations of intellectual energy, in quality or quantity. To the nervous temperament there may belong social and intellectual gifts and graces, originality, intensity, poetry, art, philanthropy. Adjusting skill, the ability to adjust their organism to their environment, to use Herbert Spencer's phrase, is often lacking.

Many of these people have the marks of Morel's *dégénérés* with few compensations; many illustrate that marvellous law of compensation in nature for defect in one direction by accomplishment in another. Often not only they, but generations before them, have been crammed mentally and emotionally but starved in other ways, their very abstemiousness producing a tough asceticism, requiring decades before the final but sure physical deterioration, or there may be a gouty diathesis and the two somewhat opposite temperaments or perhaps constitutions may be combined by intermarriage. They fail to store up nervous energy; they are unable to inhibit the free or excessive or explosive discharge of it in response to inconsequent excitations, and they are constantly in the position of having expended more than their reserve nervous force. From the prominence in adult life of the unstable emotional centres which predominate in childhood, they are most difficult to treat. Most of them are insomniacs, more or less, to quote one of the most gifted and graceful of them. We can no more relieve them of all their symptoms than we can add a cubit to their stature. But there are none in the community for whom we can do more, as there are none to whom alluring promises, including mind-cure, faith-cure, hypnotism, etc., are more seductive.

(12) Wakefulness is one of the most difficult symptoms to treat in the various stages of many forms of mental disease, and it is doubtless only an early symptom in many cases where it had been regarded as a cause. In hysteria, hypochondria, and organic dis-

eases of the spinal cord and brain, including haemorrhage, embolism and thrombosis, insomnia often taxes our utmost resources.

(13) As a form of insanity — that is, as an interchangeable psycho-neurosis in families predisposed to mental disease — insomnia is not very uncommon, especially among Morel's *dégénérescences*. In such case it is persistent for months or years, is attended with great mental and physical exhaustion from slight effort, and is most intractable to treatment. It usually ends in more or less permanent mental enfeeblement with impaired will-power and diminished self-control, perhaps without, but generally with, other psychical symptoms.³

In estimating the value of insomnia as a symptom — that is, in establishing a prognosis — it is chiefly in neurotic patients that we have great concern; and even in them it seems to me well to always bear in mind the distinction which Meynert draws between the large number *Zur Krankheit Berufenen* and the much smaller number of those *Zur Krankheit Erwählten*.

The one organ, excluding organic disease, upon the functional health of which I place the first dependence in prognosis, is the stomach.

There are certain obvious indications in the treatment of insomnia, to amend bad habits, which may mean the errors of a lifetime; to relieve painful impressions through any of the external senses; to remove depressing mental influences; to cease over-work; to interrogate every function and organ of the body; to correct constipation, faults of digestion, whether gastric or intestinal, oxaluria, etc.; to forbid unsuitable articles of food and drink; to meet the indications of toxic influences in acute and chronic disease, from the abuse of tea, coffee, tobacco, alcohol, opiates, chloral, bromides, cocaine, or in poisoning from lead, arsenic, and other sources; to stop excesses and build up conditions of exhaustion and anaemia; to control as far as possible the vascular disturbances in hepatic, renal and cardiac diseases, using leeches as needed in venous engorgement or congestive conditions.

Further than this and treating symptoms, our measures must be largely restorative — so little do we know of sleep and sleeplessness or understand the pathology of the nervous system and its cells with their molecules estimated to contain each nearly a thousand atoms grouped together in small and large clusters, which are again united into larger more or less complex groups.

The amount of sleep needed either in health or disease and the injury from loss of sleep, vary so widely in different persons that naturally there can be no fixed rule for therapeutic interference. Generally speaking, the temptation is to resort to medical treatment too readily, and to be too much afraid of a few sleepless nights. In some individuals and in some families, a wakeful week, with little sleep each night, is not a matter for concern, as compared with acquiring the habit of depending upon narcotics; in others the use of sedatives, even for a long time, is attended with good results.

³ If this classification is unsatisfactory, the latest attempted on a scientific basis does not better meet the case, stated by Germain-Sé and Gilles de la Tourette: (1) L'insomnie digestive; (2) L'insomnie cardiaque et dyspeptique; (3) L'insomnie cérébro-spastique, neurosique, comprenant les lésions de l'encéphale, la paralysie générale, les manies aiguës et chroniques, l'hystérie, l'hypocondrie; (5) Les insomnies psychiques (émotives, passionnelles et sexuelles); (6) L'insomnie psychogène, et les crises; (7) L'insomnie hystérique; (8) L'insomnie fébrile, infectieuse, autotoxique; (9) L'insomnie toxique (café, thé, alcool).

The hygiene of sleep includes the most minute attention to the whole environment of the patient, position, change of room or of locality, temperature of the body and of the air, diet, digestion, secretions, excretions, fresh air, soothing sounds or manipulations, rest and exercise accurately adjusted to the needs of the system, presence or absence of noise, relief from sources of irritation. When certain areas of the brain are over-stimulated to exhaustion with wakefulness, the exercise of other parts, diverting the attention by pleasant conversation or fixing it upon a new subject, a short walk in the open air, gymnastics, an agreeable novel, a light supper, koumyns, matzoos, malt or cautiously used wine, beer, ale, porter, spirits, are expedients which are useful, some to one, and others to another wakeful person. Change of climate, scene and association, travelling, or, better, camp-life, especially in the mountains, a sea-voyage, or a wisely selected hydro-pathic establishment will often avail. Mountain air has seemed to me best where there is increased vascular tension or diminished vaso-motor control, especially in those cases where sea-bathing, tonics, and alcohol disagree. The sea-level and a humid atmosphere, in my experience, have been useful for the anæmic, the exhausted, and those with cardiac disease. Often the most suitable climate is best determined by trying one after another. We have the authority of Marcus Aurelius for the statement that Esculapius prescribed horse-back exercise. The outside of a horse has been said to be the best thing for the inside of a man. Under any and all circumstances I endeavor to get such patients into the open air, even when they are feeble, and into the air of the woods, or the sea, or the country, if possible.

The application of cold to the head, heat to the feet or abdomen, of galvanism, faradism, dry cupping, the Paquelin cautery, Chapman's ice-bags to the spine, or prolonged hot baths with or without cold affusion to the head, may be efficacious. Massage and the wet-pack are of the greatest value, and the treatment so properly identified with Dr. Weir Mitchell's name has made the only wise and efficient management possible for a large class, although, like all powerful remedies, capable of harm with unsuitable cases or in unskilled hands.

In neurasthenia and in conditions of unstable equilibrium, nervous or psychical, particularly where alcohol and most medicines fail or have some disagreeable after-effect, personal influence may outweigh all else; a teaspoonful of water taken with confidence becomes a hypnotic, and whatever develops or creates self-discipline and self-control in the patient is a remedy of no mean value. As Ruskin says, too, people think by infection, catching a passion like a cold. For these reasons the grotto of Lourdes, faith-cure, mind-cure, Christian science, spiritualism, hypnotism, have their devotees, and charlatancy may succeed where medical skill and experience fail. The physician's reputation or confidence in him, from experience, also go to make up no small part of the personal equation and the so-called moral treatment so long used with the insane has been, especially, in the hands of masters like Bell and Ray, an immense power.

I am not fully prepared to say that hypnotic suggestion cannot be used to advantage in some cases of insomnia. The evidence thus far inclines me to the opinion of Germain-Sé and Gilles de la Tourette, that the French Ministry of War is right in interdicting its use

by the army surgeons on the soldiers, on the ground of its tendency to do harm. To many in the community there may be no corresponding or compensating harm, to others the evil is great, from such a degree and kind of suspension of the higher cerebral activities — from losing their grip, so to speak — and one cannot yet fairly estimate its general effect on the community.

It is better, especially for people of the neuropathic temperament, to overdo, and, at times, to suffer some sleeplessness in consequence, than to sink into deeper and deeper inertia while striving to avoid every effort which brings discomfort with it, or after it, just as it is not always best to shut out every sound, even if disturbing to sleep. Many do best to bear a certain amount of wakefulness, as others must suffer pain, when our help awaits much in giving strength and courage.

Stimulating tonics, phosphoric acid, phosphates, hyphosphites, quinine, strychnine, iron may prove serviceable, but certain patients exhibit a marked intolerance of medicines and alcohol.

(*To be continued.*)

EIGHT CASES OF LARGE, PULSATING ARTERIES ON THE POSTERIOR WALL OF THE PHARYNX.¹

BY J. W. FARLOW, M.D., BOSTON.

In the *Boston Medical and Surgical Journal* of March 31, 1887, I reported five cases of visibly pulsating arteries of the pharynx, which I presumed to be abnormally large ascending pharyngeal arteries. Since then I have seen seven other cases, and Dr. F. I. Knight has kindly sent me the notes of a case in his own practice.

CASE I. Mrs. M., forty-seven years of age. Some chronic pharyngitis. A large, pulsating vessel seen on the posterior pharyngeal wall, where the posterior pillar of the fauces of the left side joins the pharynx. The vessel had an oblique direction.

CASE II. Mrs. D., thirty-five years of age. Pharyngeal membrane thin and atrophic. A large pulsating vessel on the right side of the pharynx.

CASE III. Mrs. C., fifty-one years of age. A large, pulsating vessel on the left side of the pharynx.

CASE IV. Mrs. W., thirty-eight years of age. Dry throat for two weeks. A pulsating vessel on each side of the pharynx, about half way between the uvula and the sides of the pharynx. The pulsation seemed not quite as strong as in the radial of the same patient.

CASE V. Mr. M., forty-eight years of age. Pharyngeal membrane thin. A good-sized pulsating vessel on the right side of the pharynx. This is the only instance I have seen in a male.

CASE VI. Girl, fourteen years of age, sent to me by Dr. E. D. Spear. There was marked hypertrophy of the glandular tissue of the pharynx and vault and a distinctly pulsating vessel was seen on the right side. Dr. Spear had wisely congratulated himself on having noticed this vessel, otherwise, a removal of the adenoid tissue might have given rise to an uncomfortable hemorrhage.

CASE VII. Mary F., aged seventeen years. Atrophic pharyngitis. A pulsating artery on the extreme right side of the pharynx.

¹ Read before the Boston Society for Medical Observation, May 5, 1890.

CASE VIII. Lady, sixty-eight years of age, was the case seen by Dr. Knight. In the pharynx he observed the marked pulsation of two arteries, one on each side and approaching to within about one-quarter of an inch of each other. The right was decidedly the larger.

In the *British Medical Journal* of September 17, 1887, Dr. E. Creswell Baber gave an account of a case that he had seen, where there was a pulsating artery of the pharynx.

It has seemed strange to me that so large a number of such cases should come to my notice. Possibly I have been, more than usual, on the look-out for them. I am inclined to think, however, that a thorough inspection of the sides of the pharynx will bring to light a greater number of instances than have been hitherto reported.

REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M.D.

RECOGNITION OF BLOOD IN MEDICO-LEGAL INVESTIGATIONS.

FOR the extraction of blood-stains, Klein¹ recommends water saturated with carbon dioxide (Struve's process) as giving the best results. The stained spot is cut out, placed in a test-tube with two to three cubic centimetres of distilled water, and treated with a slow stream of carbon dioxide. Stains which are only a few hours old are usually completely extracted in five to ten minutes; those up to two weeks old require fifteen to twenty minutes; those up to one month, about thirty minutes and those six to eight weeks old, from thirty minutes to one hour. Whitish or yellowish masses of fibrin are left unaffected. The clear, yellowish or brownish colored solution thus obtained is examined spectroscopically. In the case of stains extracted immediately after drying, the two absorption-bands of oxyhemoglobin in the yellow and green portions of the spectrum are alone visible. If the spectrum is shaded up to the red, the methemoglobin band in the red is easily recognized. The intensity of the absorption-band in the red increases with the age of the stain, and in stains fourteen days to one month old it is nearly as intense as the bands in the yellow. Stains five or six months old give solutions in which the band in the red is, at times, the only one visible; and this was always the case in stains six to eight months old. Such old stains, after treatment with carbonic acid water for some hours, still leave behind a brownish-colored residue which, freed from adhering fluid by means of blotting-paper, gives up to glacial acetic acid or to ammonia after about ten minutes treatment a brown coloring matter whose acid solution in thick layers shows plainly the absorption-band of acid hematin. Both the ammoniacal and acetic acid solutions, when treated with ammonium sulphide and twenty per cent soda solution in slight excess, give the spectrum of reduced hematin.

Solutions of old blood-stains in carbonic-acid water, which have a reddish-brown color and show the methemoglobin band in the red, are immediately changed by treatment with an aqueous solution of hydrocyanic acid (1-2 drops of a 1-1,000 solution, or 12-15 drops of a 1-10,000 solution). The solution

¹ Zeitschrift für Analytische Chemie, 1889, page 389. Inaugural Dissertation, Dorpat, 1889.

has a reddish tinge and on spectroscopic examination only the bands in the yellow and green are visible; the methemoglobin band having disappeared. In place of this is a faint shading of the spectrum between the positions of the two oxyhemoglobin bands. Solutions of fresh blood-stains are apparently unchanged by hydrocyanic acid. The action of hydrocyanic acid possibly affords a means of determining the age of a given stain. For this purpose, the relative intensity of the absorption-bands in the red and green is determined; the band in the red is then obliterated by the action of hydrocyanic acid; the solution is then examined in a layer so thick that the violet end of the spectrum is shaded, when a conclusion may, perhaps, be drawn, in regard to the amount of unchanged oxyhemoglobin, from the intensity of the bands in the yellow and green portions of the spectrum. Solutions in carbonic-acid water which show the absorption-bands of oxyhemoglobin give, on careful treatment with ammonium sulphide, the spectrum of reduced hemoglobin. If this solution is shaken with air the oxyhemoglobin bands again appear. Finally, if a few drops of soda solution are added, the spectrum of reduced haematin is obtained.

If the stain cannot be removed by scraping, one can, after the spectroscopic examination, precipitate a small portion of the carbonic-acid solution with suitable reagents; for example, chloral hydrate, zinc acetate or tannin, and employ the precipitate for the production of haemin crystals. The author has made a special investigation of the process recommended by Ferry de la Bellone.² The carbonic-acid solutions gave immediately, upon the addition of chloral solution, a rose-colored turbidity and later a similar rose-colored precipitate, which settled completely after some hours. A drop of this precipitate gently warmed on a glass slide furnished a coagulum in which, after treatment with fuchsin and acetic acid, numerous blood-corpuscles were detected on microscopic examination. The test for haemin crystals was equally satisfactory. A small quantity of the precipitate dissolved in ammonia and treated with a few drops of a solution of ferrous sulphate and tartaric acid gave a solution which exhibited plainly the absorption-band of reduced haematin. An acetic acid solution of the precipitate furnished an equally satisfactory absorption-band of haematin. The chloral precipitate dried over sulphuric acid in a dessicator and kept for six months, furnished, on proper treatment, haemin crystals and the spectra of haematin and acid haematin as satisfactorily as did the original moist precipitate. The precipitate obtained by the addition of zinc acetate to a carbonic-acid solution of blood-stains furnished, on proper treatment, the spectrum of haematin in acid solution and of reduced haematin; but, did not, as a rule, afford haemin crystals.

If the fibrine left after extraction with carbonic-acid water is submitted to the action of water saturated with carbon dioxide for twenty to twenty-four hours and the residue is then examined microscopically, it is possible at times, especially if the blood is dried in a thick layer and not on a porous surface, to recognize the blood-corpuscles, normal in shape and size. These could be satisfactorily measured after they were treated for ten to twenty minutes with a one or two per cent. solution of perosmic acid, or, after they were colored with an aqueous fuchsin solution. An excess of the fuchsin solution can be removed by washing with water

containing carbonic acid. The diameter of blood-corpuscles from stains varied after this treatment, in human blood between 0.00748 and 0.00758 mm., in the blood of the ox between 0.00592 and 0.00624 mm.

In the case of stains more than six to eight months old from which carbonic acid fails to remove the coloring matter, other solvents may be employed; for example, dilute soda solution, acetic acid, etc.

The author describes experiments in which the foregoing process with unimportant variations was employed. In one of them some coarse sand was mixed with five per cent. of blood and examined ten years later with satisfactory results.

SUGAR AND OTHER REDUCING SUBSTANCES IN URINE.

The most important substance that reduces an alkaline solution of copper oxide, and that is apt, therefore, to be mistaken for sugar in urine, is glycuronic acid. This compound is the one which makes its appearance in the urine after the administration of chloral hydrate and croton chloral and which has been described as urochloralic acid and uronitrotolol. It also appears in the urine after the ingestion of brom-benzol, nitro-benzol, phenetol and some of the derivatives of quinine, benzol, indol, morphine and chloroform.

H. H. Ashdown, M.D., has investigated a large number of specimens of urine, in order to trace as far as possible, the presence of glycuronic acid and to differentiate it from glucose, and now publishes his results, together with a description of glycuronic acid and the method of obtaining it from urine.³

When pure this body appears in white amorphous granules; but in the state of anhydride, it forms fine, colorless acicular crystals. It is very readily soluble in water, not so readily in absolute alcohol, and scarcely at all in ether. Solutions of the acid are very readily decomposed, but they are much more stable in an acid than in an alkaline medium. In the urine it appears in combination with urea, but it is difficult to say whether uroglycuronic acid, or glycuronat of urea best represent its relation to urea; probably the former. It forms more stable compounds with barium and with lead. It holds the oxide of copper in solution in the presence of an alkali, and reduces it, throwing down the suboxide upon boiling, either in Trommer's or Fehling's test; a similar reduction occurs with the oxides of bismuth, mercury and silver. When pure it rotates the ray of polarized light to the right 35°; but many of its combinations rotate the ray to the left. It does not ferment in the presence of yeast, and thus markedly differs from glucose.

The best method to obtain this acid from the urine is that recommended by Schmiedeberg and Mayer. A large quantity of urine is evaporated to a syrup, and then digested at a gentle heat over a water-bath with a considerable excess of damp barium hydrate. It is then extracted with absolute alcohol which leaves the acid undissolved together with a number of other urinary constituents. The residue is treated with a large quantity of water and filtered; barium hydrate is added to the filtrate, which is again filtered and evaporated over a water-bath. There is thus obtained an amorphous, spongy barium compound, which is washed upon the filter with water, and decomposed by means of sulphuric acid, again dissolved in water, and evaporated *in vacuo* over sulphuric acid, when crys-

² Journal, April 4, 1880, page 337.

³ The British Medical Journal, January 25, 1890, page 169.

tals of the anhydride will be obtained. This method is not sufficiently accurate to allow of any valuable quantitative results. For definite recognition it is absolutely necessary to obtain the compound pure. The polariscope, unless used with pure solutions of the acid or with solutions of known combinations, is apt to mislead, since some of its combinations rotate the ray to the left, and others to the right; and if glucose be also present very erroneous conclusions may be arrived at. The best method of differentiating this acid from glucose is the fermentation test with yeast.

Ashdown's investigations show that the urine secreted after the administration of morphine and of chloroform, contains, not sugar, but glycuronic acid. These results confirm previous investigations of Meyer. The so-called glycosuria of curare-poisoning does not depend upon the presence of sugar; for there is no fermentation with yeast. The quantity of urine obtainable in these experiments is so small, however, that it is not possible to separate out glycuronic acid. The author has never found any reducing substance in the urine after the administration of ether. After section of the renal nerves, a paralytic secretion occurs; this contains a reducing substance which was found to be glycuronic acid. The quantity is never large, though distinctly marked. The author reports one case in which this reducing substance was excreted in large quantity. The man in whom this occurred enjoys perfect health, and does not suffer from any of the symptoms of diabetes. He however, passes daily very large quantities of glycuronic acid in a urine which is not increased in quantity or density.

Gaube⁴ has examined a large number of urines with regard to their reducing constituents, and states that in one case, that of an emaciated child, the reducing substance was aldehyde.

Professor Huppert, in a private communication to Robert Kirk,⁵ regards the uroleucic acid previously described by the latter⁶ in the urine in cases of alcapturia as a homologue of gallic acid and probably pyrogallol-propionic acid, or at least a trihydroxyphenyl-propionic acid. It does not give the genuine Millon's reaction, and therefore contains either no hydroxyl group in the benzene nucleus, or more than one; it is optically inactive, and therefore contains no asymmetrical carbon-atom.

Uroleucic acid was found to have considerable antiseptic power. It is entirely absent in normal urine. The substance previously described as uroxanthic acid, which accompanies uroleucic acid in these peculiar urines, has been more fully investigated, and found to consist simply of uroleucic acid mixed with hippuric acid as an impurity.

According to Mörner,⁷ the urine of persons taking acetanilide (antifebrin) reduces alkaline solutions of cupric hydrate and is strongly laevorotatory. This is due probably to a derivative of glycuronic acid. Chittenden⁸ finds that glycosuria is a very constant and characteristic symptom in poisoning by the salts of uranium.

In the estimation of sugar by Fehling's solution, Causse⁹ suggests the addition of 4 c.c. of a five per

cent. solution of potassium ferrocyanide, and 20 c.c. of water to each 10 c.c. of Fehling's solution employed. On running in the sugar solution to the boiling mixture, the potassium ferrocyanide dissolves the cuprous oxide as quickly as it is precipitated, and forms a colorless solution, thus rendering the exact point of decoloration more easily seen and preventing bumping. Potassium ferrocyanide appears to be without action on hot or cold Fehling's solution. On cooling the liquid obtained after titration, it turns brown and deposits colorless crystals which the author intends to study.

Crismer¹⁰ recommends a 0.1 per cent. aqueous solution of safranine as a reagent for the detection of sugar in the urine. One cubic centimetre of urine is heated to boiling with 5 c.c. of the reagent, and 2 c.c. of a ten per cent. sodium hydrate solution. If sugar is present, the safranine solution is decolorized. One milligramme of glucose in 1 c.c. of urine is sufficient to produce this effect. At the surface the color of the dye rapidly reappears, owing to reoxidation. Safranine is not reduced by uric acid, creatinine, chloral, chloroform, hydrogen-peroxide or hydroxylamine salts. Egg-albumen reduces it slowly, but completely.

Josef Geyer¹¹ has studied the relations of glycuronic acid to phenylhydrazin in order to discover whether they form any compound resembling the phenylglucosazon, formed in the phenylhydrazin test for sugar.¹² He finds that glycuronic acid and its sodium salt give, when treated in the manner recommended by Von Jakob, yellow crystals which cannot be distinguished from those of phenylglucosazon. He also examined the urine in fourteen cases, and although all of these contained a substance resembling phenylglucosazon, and reacted positively with Trommer's test, only four responded to the fermentation test and rotated the ray of polarized light to the right. He concludes, therefore, that the phenylhydrazin test is not a reliable one for sugar, and that the fermentation test and the test with the polariscope are the only reliable ones. Hirschel, however, has investigated this question and has reached a different conclusion.¹³ He finds that urines free from any sugar usually give with the phenylhydrazin test an amorphous, yellowish-brown, or brown precipitate which cannot be mistaken for the phenylglucosazon crystals. This precipitate is apparently a compound of phenylhydrazin with glycuronic acid. Hirschel believes that sugar is certainly present if characteristic phenylglucosazon crystals are obtained.

Torsellini¹⁴ finds that the reaction for glucose with the copper and bismuth solutions is masked or prevented by the addition of a relatively large amount of saccharine; but that the reduction is not prevented if one employs an excess of the reagent, or if the saccharine is first neutralized by sodium bicarbonate. Inasmuch as saccharine does not modify the rotatory power of glucose, he advises the employment of the polariscope for the determination of sugar in the urines of patients who are taking saccharine.

UROBILINURIA.

M. Hayem¹⁵ considers that urobilinuria, when ha-

¹⁵ Paris Correspondence, British Medical Journal, January 4, 1890, page 43.

bitual, persistent, and varying in degree, has a clear pathological significance, and is a valuable indication in forming an early diagnosis in diseases of the liver. He regards urobilin as the characteristic coloring matter of hepatic incompetency. He has observed urobilinuria in the following cases: (1) At the beginning of alcoholic cirrhosis. (2) In cardiac patients in whom the liver is not enlarged, it may be an indication of incipient hepatic lesions. (3) In numerous acute affections when observed in alcoholic patients, such as typhoid fever. When a large proportion of urobilin is detected in this affection, reserve should be made with regard to the prognosis. (4) In newly delivered and nursing women. (5) In most forms of cachexia. Urobilin has a feeble coloring power, and is found in pale urine. The deep coloring of urine observed in certain affections (fever with perspiration, lassitude, overfatigue) is usually due to urochrome.

THE URINE IN MELANURIA.

R. v. Jakob¹⁶ describes the examination of the urine in two cases of melanuria. The cases were patients suffering from melanotic sarcoma; in each case the urine contained a dark brown pigment. The following are the chief conclusions drawn: The most delicate reagent for detecting melanuria is a very dilute solution of ferric chloride; this colors the urine black. In urine containing melanin or its chromogen (melanogen), prussian blue is formed when the urine is mixed with a nitro-prusside and aqueous potash, and an acid added. The prussian blue reaction does not seem to depend on the presence of melanin or its precursor; these substances do not give the reaction when they are separated from the urine; it must, therefore, be due to some other substance excreted at the same time, and apparently some substance which is present in minute quantities, even in normal urine. The same substance is also abundant in urines which are rich in the indigo-yielding material.

PRECIPITATION OF ALBUMINS BY INDIFFERENT BODIES.

When urine is cloudy from the presence of bacteria, it is exceedingly difficult to obtain by filtration a liquid sufficiently clear to permit the detection of slight traces of albumin. Boymond¹⁷ has made many experiments, hoping to discover some comparatively insoluble substance which may be employed as an aid to such filtration. He found that a perfectly clear and partially decolorized liquid may be obtained by simply shaking the urine for awhile with washed talc and then filtering; but when urine, containing at the same time serine and globulin, were thus treated, the globulin was wholly removed, and possibly a portion of the serine. He then extended his researches to other substances; washed animal charcoal, carbonate of lime, phosphate of lime, carbonate of magnesium, calcined magnesia, and subnitrate of bismuth. The result was the same, with this difference, that subnitrate of bismuth removed completely both serine and globulin. Boymond proposes to continue his researches and extend them to other classes of "indifferent" substances. He calls attention at this time, however, to a possible source of error, which is obvious, in treating urines in this manner as a preliminary to the test for albuminous sub-

stances, and suggests that urine, deprived of serine and globulin by means of subnitrate of bismuth, may serve for the determination of other constituents, and that talc, either alone or in conjunction with magnesium sulphate, may be employed to precipitate globulin; affording at the same time a liquid perfectly clear, and more suitable for the detection of serine.

IODOFORM.

Choay and Gautrelat¹⁸ find that, following the internal administration of iodoform, only decomposition products of iodoform are found in the urine in those conditions which are attended with the excretion of an alkaline urine. On the other hand, in those conditions in which the process of oxidation taking place within the body is diminished, and in which an acid urine is excreted, iodoform is always present as such in the urine and can be removed by shaking the urine with ether, which leaves characteristic iodoform crystals upon evaporation.

POISONING BY TINNED CHERRIES.

Arthur P. Luff, M.D., and G. H. Metcalfe¹⁹ report four cases of tin-poisoning caused by tinned cherries. These cases are of special importance in that the form in which the tin was carried into solution was ascertained by analysis, and the amount of soluble tin salt present in the cherry juice was quantitatively determined. The patients were adult males. The symptoms of poisoning made their appearance in from one and a half to two hours. The local irritant symptoms were abdominal pain, vomiting, diarrhoea, and in two of the cases a transient albuminuria. A feeble, irregular, and rapid pulse, together with marked collapse and cyanosis, were prominent symptoms in all the cases. As a result of appropriate treatment, all the patients were practically well in twenty-four hours. The cherry juice was strongly acid, and analysis showed that the acidity was due to malic acid with a small quantity of acid tartrate of potash. The juice contained tin in solution, a quantitative estimation of which, showed that each fluid ounce contained the equivalent of 1.9 grains of the higher oxide of tin, which would be equal to 3.2 grains of the malate of tin in each fluid ounce, or 60.4 grains in a pint. As far as could be estimated from accounts given by the patients of the number of cherries and the amount of juice they took, the symptoms must have been produced by doses of the malate of tin varying from four to ten grains.

SEPARATION OF STRYCHNINE FROM BRUCINE.

J. E. Gerock²⁰ describes a method which is based upon the fact that brucine is much more sensitive to the action of oxidizing agents than strychnine is, and that the products of the oxidation of the former alkaloid fail to give precipitates with the general reagents for the alkaloids. Brucine undergoes this change when heated on the water-bath with nitric acid of specific gravity even below 1.06; while strychnine treated in a similar manner with nitric acid of specific gravity below 1.131 undergoes no change whatever.

The following is the method of procedure recommended. The alkaloids are gently warmed and precipitated from a neutral solution by means of picric

acid. After remaining for some time, the precipitated picrates are collected on a tared filter, washed with cold water till the washings become colorless, dried at 105°, and weighed. The precipitate is transferred so far as is possible to a beaker, and those portions remaining on the filter-paper are repeatedly treated with nitric acid of specific gravity 1.056, previously warmed on the water-bath. This nitric acid is then transferred to the beaker which contains the rest of the precipitate, and the mixture is warmed on the water-bath for some time. The picrate of brucine is destroyed, while the picrate of strychnine is dissolved without undergoing chemical change. The solution is then exactly neutralized and a trace of acetic acid is added. After cooling the picrate of strychnine is transferred to the same filter as before, washed, dried, and weighed. From the difference in weight, the quantity of brucine can be calculated.

STRYCHNINE-LIKE PTOMAINES.

Jeserich²¹ describes a ptomaine, which, like veratrine, was colored red by hydrochloric acid, and gave no reaction on the further addition of concentrated sulphuric acid; but with potassium dichromate and sulphuric acid it gave a color-reaction resembling in every particular the reaction given by strychnine with the same reagent. It did not, however, cause tetanic convulsions when injected subcutaneously in a frog.

White²² has extracted from food by the Otto-Stas process an amorphous substance which gave, with sulphuric acid and oxidizing agents, a purple color similar to that given in the strychnine test. The alkaloid was however tasteless. It was soluble in water, alcohol and ether; the aqueous solution was not alkaline; it gave a precipitate with phosphomolybdic acid and with a solution of iodine in potassium iodide, but no reaction with nitric acid or with ferric chloride.

NICKEL.

Rohde²³ has investigated the action of organic acids on nickel. Nickel utensils were exposed to the action of two and four per cent. solutions of lactic, acetic, citric, tartaric and butyric acids, both cold and hot. He concludes that the quantity of nickel dissolved by these acids is altogether too minute to have any appreciable effect on the system, and that utensils made of nickel may be safely used for household purposes. The results of Rohde's researches corroborate those of Riche, which have already been noticed in these reports.

DESTRUCTION OF ORGANIC MATTER IN TOXICOLOGICAL INVESTIGATIONS.

F. Marino-Zucco²⁴ recommends covering the substance with concentrated nitric acid and then passing nitrogen tetroxide into the mixture, heat being applied when the liquid has become green. One kilogram of meat may be completely destroyed in half an hour, and the fat may be removed from the surface after cooling. Experiments with definite quantities of arsenic, copper and zinc showed that the method is well suited for the purpose.

Reports of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

The Twelfth Annual Congress of the American Laryngological Association convened in Baltimore, May 29th, 30th and 31st, in the lecture-room of the physical laboratory of Johns Hopkins University, Dr. JOHN N. MACKENZIE, of Baltimore, presided.

The following Fellows responded to roll-call by the Secretary, Dr. C. H. KNIGHT: Drs. Morris J. Asch, New York; F. H. Bosworth, New York; Wm. H. Daly, Pittsburgh; D. B. Delavan, New York; F. Donaldson, Baltimore; J. H. Hartman, Baltimore; F. W. Hinke, Buffalo; Edgar Holden, Newark; E. F. Ingals, Chicago; W. C. Jarvis, New York; C. H. Knight, New York; S. W. Langmaid, Boston; A. W. MacCoy, Philadelphia; J. N. Mackenzie, Baltimore; H. C. McSherry, Baltimore; J. C. Mulhall, St. Louis; C. C. Rice, New York; J. O. Roe, Rochester, N. Y.; C. Seiler, Philadelphia; H. L. Swain, New Haven; S. O. Vander Poel, New York; B. F. Westbrook, Brooklyn.

One new member was elected, Dr. Jonathan Wright, of Brooklyn. The sessions were held twice daily, on the first two days; the final session on Saturday morning was held in the library of Johns Hopkins Hospital.

THE ANNUAL ADDRESS.

was delivered at the opening session Thursday morning by the President, DR. JOHN N. MACKENZIE, in which he alluded in complimentary terms to the scientific work done by the Fellows during the past year. No deaths among active Fellows had occurred during the year. The death of Voltolini, one of the pioneers of laryngology and a Corresponding Fellow of this Association, was referred to in appropriate terms. The great advances in laryngology made during the last few years, the increase in the number of those engaged in its practice, and the greater attention given to its teaching by medical schools, may make it advisable at a future meeting to enlarge the membership which now is limited to fifty, but the time had not yet arrived. A favorable mention was made of the Congress of American Physicians to be held next year in Washington, in which this Association will participate. The attention of Fellows was also called to the condition of the library, and they were invited to contribute their publications to this collection, in order to build up a valuable library, for which they have special opportunities.

A SUGGESTION CONCERNING THE INTIMATE RELATIONSHIP BETWEEN BULBO-NUCLEAR DISEASE AND CERTAIN OBSCURE NEUROTIC CONDITIONS OF THE UPPER AIR-PASSAGES,

was the title of a paper substituted by DR. JOHN N. MACKENZIE, of Baltimore, for that which had been announced upon the programme.

The reader stated that the reciprocal relationship between lesions of the central nervous apparatus and certain morbid phenomena exhibited in the upper respiratory tract, is a subject of surpassing interest, and one, strange to say, upon which comparatively little original work has been done. There has been too great a tendency for specialists to confine research within exact anatomical limits, and within too contracted a sphere of observation. The text-books give

very little attention to this interesting class of cases, and what is given is in terms vague and indistinct. Functional aphonia, and the affections which Sir Morell Mackenzie has named "spasm of the tensors of the vocal cords," are illustrations. What do we know concerning the pathology of either of these? They are expressions of some central trouble, but we know absolutely nothing of their primary cause or essential nature. The close nervous relations existing between the nasal chambers and the medulla and sympathetic nervous system, the lecturer had had occasion to refer to in previous communications, and would not further discuss. The present paper refers especially to bulbar lesions with symptoms of disorder in the upper air-passages. The case reported was that of a widow aged about forty, whose husband had been a drunkard, who had died about a year before she came under observation. Her own habits had been always good; she had not been infected by syphilis. She had been subjected to much mental strain and worry, and, although she had not been nervous previously, her friends had noticed that she became so after her husband's death. A short time subsequent to that event, while at house-work, her face became suddenly drawn to the left, especially the corner of the mouth. No difficulty in articulation occurred, and in three days the attack passed off. After an interval of perfect health, she was attacked by partial loss of power in her right hand, with loss of sensation; there was tingling in the lower extremities without loss of power. This tingling sensation was also felt in the throat. She attributed the attack to over-work; she having carried wet clothes on her arm the day previous. These symptoms gradually disappeared; but a difficulty in articulation ensued, without aphasia; mouth again drawn to one side (the left). Several weeks after these symptoms had subsided, while sweeping her room, she was seized with foaming at the mouth, and puffing out of the cheeks, with tingling in the right hand. She could only mumble a few unintelligible words. No fall or convulsion. She walked up stairs to bed. Legs were swollen. About six weeks later she had slight dysphagia, pain in the back of the neck and shooting pains in the hands. These symptoms also passed away. When she came under observation there was slowness in movement of the tongue; it could not be lifted to the roof of the mouth, nor above the upper lip. The mouth was drawn at the angles; could not whistle nor kiss, nor blow out a candle at a greater distance than a foot from the mouth. Some difficulty in mastication, and in facial muscles, in movements of the muscles of expression. Complete paralysis of soft palate and uvula; reflex excitability there and in the pharynx notably diminished. Voice had nasal twang. Rhinoscopic examination negative. Saliva thick, tenacious; difficulty in expectorating; requiring its removal with the finger or handkerchief. General muscular weakness, without paralysis. Temperature normal, respiration 30. Slight dyspnoea, much increased by exercise. Patient has hysterical spells of noisy crying and laughing.

The patient was only seen once; because she received an unfavorable prognosis, she never returned. Sufficient data, however, were obtained to demonstrate the bulbar-nuclear nature of the case. If in this class of disorders, neurologists and laryngologists could work together, more light would doubtless be thrown upon their pathology.

DR. BOSWORTH: considers the case as one of neuritis, especially of trifacial, and could not see why it should be called one of bulbar disease. Moreover, if the latter, it would be necessary to determine what form; whether a clot or a thrombus, or softening or a tumor. The diagnosis of bulbar disease is not enough.

DR. DELAVAN: ever since Gottstein directed our attention to the throat symptoms of bulbar disease, there has been a tendency to refer all cases of nervous origin to a central lesion. Many of these cases are of bulbar disease, but it is possible for the central lesion to be other than bulbar. Indeed, cases have been reported where it was shown to have been cortical. While we may not at present be able to clinically differentiate these cases, yet it is very possible that we shall be able to do so in the future, by the combined work of neurologists and laryngologists.

DR. BOSWORTH: was not aware of any well-established case in which laryngeal paralysis was caused by a cortical lesion; no case in which it was shown, by post-mortem, conclusively, that the cause was not in the bulb, but in the brain. Long before Gottstein, Hughlings Jackson had shown that in some cases of laryngeal paralysis the lesion is in the medulla.

DR. DELAVAN: It has been demonstrated that cats, dogs and monkeys have a cortical centre for the movements of the larynx, and it is probable that it exists also in man, though less developed perhaps. In some cases the bulbar lesion is demonstrated after death; in others no such lesion can be found; and the cause must lie in the hemispheres, more or less deeply in the cortex, as suggested by Ferrier.

DR. BOSWORTH: The psychical centre must lie in the cortex. This can be conceded, but the motor centre for the larynx is in the bulb. This subject he had discussed in a paper read at the last meeting of the Association, and had gone over the whole subject. There are but two forms of laryngeal paralysis. We have no other forms.

DR. MACKENZIE: The case corresponds clinically with other cases of bulbar disease, and cannot be explained on the ground that it is a neuritis, especially of the trifacial, unless the nerve is distributed to the back of the neck and the lower extremities as well as to throat and larynx. He thought that the last speaker had misunderstood, or failed to hear the history of the case, and requested him to look over it carefully, and he would find the diagnosis of neuritis untenable.

In the absence of the author, Dr. Jarvis was appointed to read a paper by DR. S. SOLIS COHEN, entitled

LOOK BEYOND THE NOSE.

It was a plea for the broader view of the cause of diseases in the nasal chambers and their relation to general symptoms. Cases were reported showing mistakes in diagnosis, where headache and other symptoms, not relieved by operation, were promptly cured by general treatment.

DR. ROX: A headache, of course, always indicates that something abnormal is going on; but when any man attempts to ascribe all headaches to one source, he also is abnormal. The causes are varied. Of two cases, both presenting affections of the nose or nasopharynx, and treated precisely alike, one will be entirely relieved, the other will not be cured until he has appropriate constitutional treatment for the concurrent disorder. He cited a case of his own. An

operation had relieved a headache which had been troubling the patient for three or four years. There was marked pressure between the middle turbinated bone and the septum, which he had relieved. The facts of Dr. Cohen's paper go without saying.

DR. JARVIS agreed with the last speaker, that we could not account for the fact that nasal obstruction is attended by nervous symptoms, such as headache in some persons and not in others. While reading Stanley's account of the expedition in Africa, he noticed that the blacks were quite unmindful of even serious wounds, and seemed to recover with little disturbance of health. This led him to formulate a theory that might explain the problem stated above. The ancestors of the blacks had been accustomed to being wounded, and to have their flesh cut or scratched in going through the undergrowth, so that after a number of generations the nervous system became less irritable. In civilized life, among the higher classes, protected as they are from physical injury, the nervous system becomes more susceptible. He has known a slight amount of nasal obstruction in a brain-worker to produce a great deal of distress, headache, etc. The same lesion might be entirely unattended by nervous symptoms among the lower classes. The difference consists in the increased susceptibility of the nervous system to peripheral impressions.

DR. BOSWORTH: It seems like an indictment of the members to imply that they do not look beyond the nose. As competent specialists we all do look beyond the nose.

The PRESIDENT endorsed the last remark, and thought that no discussion was required upon the paper. It appealed to the common sense of every person of intelligence.

AN INSTRUMENT FOR REMOVING GLANDULAR HYPERTROPHIES FROM THE TONGUE.

The presentation of instruments being in order, DR. ROE exhibited a guillotine, made on the principle of the tonsillotome, for removing hypertrophied adenoid tissue from the dorsum of the tongue.

DR. BOSWORTH said that there was danger of cutting off the epiglottis in unskillful hands; and several Fellows declared that they had never seen a case that would require the employment of such an instrument, and said that hypertrophied glandular tissue at the base of the tongue is a very rare condition.

DR. ROE said that the accident need not occur if ordinary care be employed in using the instrument.

WIRE-LOOP CURETTE FOR REMOVING ADENOID NEW GROWTH FROM THE PHARYNX.

DR. HOLDEN, of Newark, exhibited an instrument consisting of a flexible wire-loop fixed in a handle, the loop being sharp upon its inner or concave side, dull upon its convex side. He had found it very useful in removing vegetations from the pharynx, acting very much like the finger nail.

DR. DELAVAN presented several instruments designed for the removal of adenoid hypertrophies or fibroids from the pharynx. One was a loop-shaped steel instrument, cutting on the inner side, the other being a sharp spoon, both being employed preliminary to using the forceps for the removal of these growths in young adults.

In the opening of the afternoon session, DR. MORRIS J. ASCH, of New York, read a paper describing

A NEW OPERATION FOR DEVIATION OF THE NASAL SEPTUM.

He used (1) a peculiar shaped pair of forceps, or scissors, with short, curved blades, one of which is sharp and the other dull; (2) a gouge; (3) Adams's forceps; and (4) a triangular splint of tin, cut to adapt itself to the cartilage of the section. In performing the operation, the patient is etherized, the adhesions between the septum and turbinated body, when such exist, are broken up by the curved gouge. The blunt edge of the scissors is inserted into the obstructed nostril and the cutting blade into the other. A crucial incision is then made as near as possible at right angles to the point of greatest convexity. The gouge is then inserted into the obstructed nostril. The segments made by the incision are pushed into the opposite one and the pressure continued until they are broken at their base and the resiliency of the septum destroyed. On this point depends the success of the operation, for unless the fracture of these segments is assured, the resiliency of the cartilage will not be overcome, and the operation will fail. The septum is then to be straightened with the Adams or other strong forceps and the hemorrhage checked before proceeding farther, which is usually accomplished by a spray of ice-water, though sometimes tamponing may be required. The nostril having been cleansed, the straightened septum is then held in position by the splint, previously wrapped with absorbent cotton, moistened in a solution of bichloride of mercury (1-5,000), and the nostril packed with gauze or absorbent cotton, moistened with the same. This should be done thoroughly or hemorrhage will follow. The splint is usually allowed to remain four days without being disturbed, and then removed; and after cleansing and disinfecting the parts, the splint and tampon are then reapplied, the parts being straightened, if necessary, with the forceps. The treatment lasts from three to five weeks. If bony deviation is found to exist behind the cartilaginous one, it can be easily removed with the saw or electric trephine. Six cases were appended to the paper.

DR. MULHALL, of St. Louis, remarked that he came from the city of Dr. Steele, who was the inventor of the instrument for treating these cases, known as Steele's forceps, which he used in fifteen or twenty cases. Although not entirely pleased with it, he approved of the plan submitted by the lecturer, of restoring the parts with a single incision. Steele's forceps makes six cuts. He had often had persistent perforation at the centre of the crucial incision, and should give Dr. Asch's instrument a trial.

DR. JARVIS said that in order to prevent the perforation, above mentioned, after operation, he had modified the forceps so that while the six incisions were made, an island in the centre was left untouched. With this he had never had perforation resulting. In order to keep the channel open he had discarded plugs, and resorted to an external nasal splint which he had devised some time ago.

DR. INGALS said that the principle of the instrument was not new. He had learned at college to make two parallel oblique incisions through the septum, so as to make it movable and place in proper position. In nineteen out of twenty of these cases there is excess of tissue, and he advocated the removal of a triangular piece between the incisions, so as to

permit the septum to fall into position. Where there is no hypertrophy, he would prefer to use a small trephine, making three or four perforations, and then the septum can readily be moved into position and kept there with some sort of splint. His own practice was to pack the affected side with absorbent, antiseptic gauze, leaving the opposite nostril free. The dressing is changed in twenty-four hours by the patient and a douche used, before returning to the office. He then introduces a flattened tube of gutta percha, fitted to the nostril; he prefers gutta percha to a soft rubber or ivory because it does not swell and cause pressure. The gutta percha may be wrapped around with gauze, if desired. It is easily moulded, when heated, to any shape.

DR. ROE said that where the deviation was limited to the cartilaginous septum, he was in the habit of dividing it with a bistoury in the direction of greatest convexity, then forcing it into position with Adams's forceps, or a similar instrument, rather over-correcting the deformity. When the deviation exists also in the bone, he breaks it up with the forceps, and uses a gauze antiseptic plug in the affected side. In this way he almost always had good results. When an exostosis exists it should be removed.

DR. BOSWORTH complimented Dr. Asch upon bringing out such an ingenious instrument, which not only corrects a vertical displacement, but a lateral one as well.

DR. MACKENZIE said that with Steele's instrument he failed to cut through the septum. He had used a modification of these forceps made in Philadelphia, which had answered his purpose fully. He approved Dr. Roe's suggestion to remove a portion of the cartilaginous septum when hypertrophied, in order to get a permanent result. His cases did not bear plugging of the nostril, and he considered it unnecessary. The septum cannot be kept in place by pressure. If anything of the kind is used, it should be cotton wet with glycerine or vaseline. With regard to the hard plug, he had seen unilateral convulsions caused by an ivory plug, this was repeated several times. He considered the after-treatment the most important.

DR. LANGMAID said that it did not matter so much what means were used to break the septum, the object of treatment is to prevent the recurrence of the deformity. He would emphasize the fact that after the operation the septum must remain in position of itself without pressure. He preferred a small black rubber nipple, wrapped with cotton, for a plug, and adapted to the shape and size of the nostril. He approved of Dr. Mulhall's suggestion, that patients should occasionally introduce a finger into the nose and push the septum over where there is a tendency to recurrence.

DR. JARVIS: With regard to the external nasal splint, although he had used it formerly in many cases, he had not used it lately. He now uses a new crown drill, with which he pulverizes the bony obstruction, guided by transfixion needles so as not to perforate the septum. In this way he secures enough room for the septum to fall into good position, and give good flow of air through the nostril.

DR. BOSWORTH considered it unjustifiable to remove an organ of important functions simply for the purpose of admitting more air into the nose.

DR. MULHALL defended Steele's forceps against the charge that they would not go through the septum. He had not found this difficulty where there was no

hypertrophy. Where there was this complication, he reduced the hypertrophy first. While there was a tendency to return after the operation, he had never seen it so decided as at first — never complete closure.

DR. INGALS: The resiliency of the septum must be gotten rid of before the operation is finished; after this, the treatment is very simple. He has had patients wearing a plug for six weeks. Where there is great thickening, he advised running a small trephine through it several times, without perforation, until it can be easily pushed over to the other side.

DR. MACKENZIE said, in reply to Dr. Mulhall, that he referred to deformed, and not thickened septa; Steele's forceps would not cut through ordinary thick paper, whereas those he referred to would cut six thicknesses of chamois skin.

DR. DALY said that he had not experienced any difficulty with Steele's forceps. He does not stop with one incision, but cuts the septum in several places. The object is to break up the cartilage, it is not necessary to perforate the septum.

DR. ASCH, in closing the discussion, said that in the paper he had declared that the success of the operation depends upon breaking down the resiliency of the septum; this being done, the splint is introduced. If it is plugged lightly with cotton, there is no trouble whatever. With regard to his instrument, he had been led to it by his failure with Steele's. In Jarvis's plan, the resiliency of the cartilage is not destroyed, and the deformity will return. He had never had septic symptoms after the use of the plug.

DR. DALY described his method of plugging the nostril with absorbent cotton, wrapped spirally with cotton thread, so that the entire plug could be easily removed.

The PRESIDENT remarked that the whole discussion turned upon the necessity of overcoming the resiliency of the septum in order to secure a permanent result. This point he had already insisted upon in a paper read before the Association some seven years ago.

DR. HOLDEN referred to a case of a young lady, upon whom repeated operations had been done without entirely overcoming the deformity. The septum in this case was then movable and crackled like parchment under the finger. The last operation with Steele's forceps, followed by ivory plug, had straightened the septum, but had left an ugly excrescence in the nostril, which he proposed to remove with the drill.

DR. ALEXANDER W. MACCOY, of Philadelphia, presented a specimen, and read a report of

A CASE OF FIBRO-MYXOMATOUS TUMOR TAKEN FROM THE NASO-PHARYNX OF A CHILD SIX YEARS OF AGE.

This is the first case that had come under the lecturer's attention in so young a child, although he had seen a polypus in a child under one year of age. Myxoma in the nasal chambers presupposes catarrhal inflammation, and this is why it is so rare in childhood, because few have had chronic inflammation of sufficient duration to develop the pathological changes necessary for the growth of polypi. The tumor in this case filled the naso-pharyngeal region, but did not come below the soft palate. The attachment was about half an inch in diameter, the growth springing from the free surface of the vomer. It was removed by the galvano-cautery snare; the wire was passed

through the nostril and around the base of the growth, and the pedicle cut through. There was trifling amount of haemorrhage. Recovery prompt and complete. The growth, upon microscopic examination, possessed the characters of a fibro-myoma.

The PRESIDENT said that he had previously published the notes of two cases of myxoma in children, and had referred to them in his article in Keating's "Cyclopaedia of Diseases of Children." They occurred in the same family, in a brother and sister, one four years of age, the other six. He removed both with the cold-wire snare. Morrell MacKenzie did not meet with a case under the age of sixteen years. Voltolini reported a case of polypus in a very young child; such instances are apt to turn out to be simply hypertrophies.

DR. SWAINE had seen a case in a child eight years of age of fibro-myxoma, just before leaving Germany; he did not know the outcome of it.

DR. BOSWORTH said that the tumor seemed to present the usual appearance of a fibro-myxoma; being encapsulated.

(To be continued.)

AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.¹

SECOND DAY.—WEDNESDAY, JUNE 4TH.
MORNING SESSION.

A CASE OF SUCCESSFUL NEPHRECTOMY FOR ADENOMA.

By DR. E. L. KEYES, New York.

A CASE OF SEVERE HÆMaturIA; NEPHRECTOMY BY DR. McBURNEY; RECOVERY.

By DR. F. TILDEN BROWN, New York.

Woman of twenty-six; married; three children; previous health good. Came of gouty family; three attacks of haematuria, first in March, 1888, second in August, 1888, and third in October, 1889. First two attacks recovered from in a week on the average. First attack diagnosed rupture of a renal vessel; second attack diagnosed by a different physician as renal calculus; third attack diagnosed by Dr. Brown as renal calculus, and nephrotomy was undertaken by Dr. McBurney for the removal of the calculus. Thorough exploration failed to reveal a calculus and the importance of immediate nephrectomy to check fatal hemorrhage was apparent and at once performed. The operation was followed by a critical condition especially marked on the third day. Relief from hot air and steam bath in bed. Six days later miscarriage at about second month. Considerable loss of blood. Patient again prostrated, but slowly rallied and made complete recovery. Wound entirely healed by December 15th. Operation, November 5th. The other kidney had been equal to all physiological requirements. Histological examination of the entire specimen by Dr. Delafield showed only chronic pyelitis attributed by him to the former presence of a calculus sometime since passed, probably in the earlier clots of the first attack, but leaving an inflamed condition of the pelvis sufficient in his opinion and by clinical experience to account for this severe haematuria. It was on this account that the case was reported.—

¹ Report of the Fourth Annual Meeting, at Altoona, Pa. Continued from page 636 of the last number of the Journal.

this heretofore unrecognized variety of kidney lesion capable of such severe hæmaturia. The author would suggest "chronic pyelitis, with acute hemorrhagic exacerbations" as an appropriate name for this disease.

DR. BELFIELD thought Dr. Brown's case unique, and the procedure undoubtedly correct, owing to the obscurity of diagnosis.

DR. A. T. CABOT said he noticed in Dr. Brown's case that, in putting on the ligature, the ureter was included with the vessels. He cited a case in which he had adopted that plan, and although the stump was sufficiently long, and all possible care taken in tying, yet on separating the kidney from the vessels, there was a tremendous hemorrhage from the artery, which was with difficulty controlled. The patient lost a dangerous amount of blood, and lived only about twenty-four hours. Post-mortem examination showed no injury to any vessels, except the renal vessels and the hemorrhage was due to the drawing of the stump out of the ligature.

DR. F. TILDEN BROWN said he fully appreciated the warning of Dr. Cabot, but in his case the condition of the patient was such that it rendered every moment of importance.

DR. BRYSON had been accustomed to attach great importance to the specific gravity of the urine, as to the diagnosis and as to the favorable or unfavorable nature of the prognosis.

DR. BROWN stated that the specific gravity was suggestive of a decidedly gouty condition; but, on the other hand, there were no crystals of oxalate of lime or uric acid found which seemed rather a contradictory condition. After the operation the specific gravity fell, was low throughout recovery, and since recovery had been rather lower than normal.

DR. A. T. CABOT read a paper on

A CASE OF CYSTITIS, WITH THE FORMATION OF A THICK EPIDERMAL SHEET IN THE BLADDER.

DR. J. W. WHITE thought this case belonged in the class of cases which Guyon had described as "membranous cystitis." Guyon had reported a number of cases in which even more extensive formation of membrane had occurred, and in which the pathological condition was practically the same. If one were quite sure of the diagnosis, and if the disease had reached the stage it had in Dr. Cabot's case he thought the suprapubic was undoubtedly the best method of procedure. We could hope for very little from washing out the bladder or from internal remedies, although in certain of Guyon's cases large quantities of the membrane had been passed spontaneously with at least temporarily complete relief.

DR. WATSON stated that he had had this patient under his care before Dr. Cabot took charge of the case, and that he was able from the urine to make a diagnosis of new growth but no new growth he knew anything about. If one knew there was this condition present it seemed to him the suprapubic operation was the only one one would care to try, because it was not like having an isolated tumor which could be reached through the perineum. One had to peel this off. It was very dense.

DR. BRYSON said in those cases of exfoliative cystitis he had seen especially in women, there was more fibrinous admixture, more like the diphtheritic membrane than this seemed to be.

DR. A. T. CABOT presented specimens of the epidermal sheet in this case. The sheet did not seem to resemble the fibrinous sheets he understood to characterize the cases of Guyon. This was a thickened epidermal sheet and not a fibrinous sheet from the surface of the mucous membrane. The inflammatory element was very strong in Guyon's cases and not in this.

A CASE OF SUPRAPUBIC LITHOTOMY AND PROSTATECTOMY,

by DR. J. WILLIAM WHITE, Philadelphia, Pa.

J. S., sixty-eight; family history of tuberculosis; always a moderate drinker; recently intemperate; urinary symptoms six years; catheter required at intervals for eight years. For four years unable to urinate without catheterization. Progressively increasing pain in hypogastrium, now (1889) excruciating and felt also at end of penis and in rectum. Lost much flesh; chronic bronchial cough. Eats and sleeps poorly. Urine scanty, loaded with pus and vesical debris, contains hyaline and granular casts. Physical examination per rectum; enlarged prostate both laterally and longitudinally, the finger being unable to reach its upper limit. Bladder contains a soft phosphatic stone of medium size. Mitral murmur bronchial catarrh; beginning consolidation at left apex. Operation, December 11, 1889. Linear incision two and one-half inches long in linea alba just above the pubes. Stone crumbled under the touch of forceps and was removed by the finger and a scoop. The major portion of the projecting prostate removed by enucleation with the finger. Large drainage-tube inserted into the bladder and held in place. Outlook most favorable for three days. On the fourth maniacal delirium, excessive restlessness, wakefulness, jactitation, etc.; refused food, tore off dressings and had to be kept in bed by force. Tongue became dry and dark; pulse increased in frequency; no chill, sweating nor rise of temperature. Urine continued to flow through the wound which was irrigated daily with boric acid, listerine or phenol sodique. Patient passed into a stupor and died seven and a half days after operation. Autopsy: ureters distended to nearly size of wrist, kidneys almost completely disorganized containing multiple purulent collections, showing scars of previous abscesses and rendered almost useless by chronic nephritis. Tubercular changes in lungs.

Dr. White offered some criticisms upon his course stating that in view of the kidney disease probably he should have been content with suprapubic lithotomy; and that possibly the use of chloroform would have been better in this case; also that after he had decided upon prostatectomy a less thorough operation might have been advisable.

NOTES ON THE TECHNIQUE OF SUPRAPUBIC CYSTOTOMY AND PROSTATECTOMY,

by DR. W. T. BELFIELD, Chicago.

The reader summarized his method of procedure as follows:

- (1) Body upon inclined plane; pelvis eight or ten inches above shoulders.
- (2) Bladder moderately distended.
- (3) Rectum not distended.
- (4) Incision about one and one-half inches above upper border of symphysis and extends same distance below it.

(5) After division of deep fascia, finger inserted along posterior surface of symphysis until pubo-prostatic ligaments reached, then pushes prevesical fat upwards along anterior surface of bladder carrying peritoneal fold, if present, with it.

(6) Bladder attached to upper angle of wound by suture preferably through muscular coat only; chrome catgut suture then inserted so as to make a subsequent quilt suture. Incision in bladder is close to symphysis.

(7) After necessary intravesical manipulation the *buttonniere* is made. Tube one-half inch in diameter with two large lateral openings introduced over large uterine sound to the most dependent portion of the bladder and fixed by stitching through skin.

(8) Bladder wound closed by the quilt suture already inserted and by several additional interrupted sutures. Retro-pubic space irrigated. Iodoform gauze inserted; wound closed and dressed aseptically.

A NEW MEANS FOR THE REMOVAL OF INTRAVESICAL GROWTHS THROUGH A SUPRAPUBIC CYSTOTOMY,

by DR. F. S. WATSON, Boston.

REMOVAL OF THE THIRD LOBE OF THE PROSTATE, WITH COMPLETE RESTORATION OF THE FUNCTIONS OF THE BLADDER,

by DR. F. N. OTIS, New York.

O. P. B., came under observation, October, 1889, with a history of frequent urination dating back ten years. In early youth a slight urethritis. Two years ago marked diminution of size of stream of urine, and pain in urination. On examination, stricture found, to which his urinary difficulty was solely attributed. Internal urethrotomy. More easy flow of urine, but no relief to symptoms. Urine became purulent; pain after urination increased; and after some months severe spasms, referred to neck of bladder. Examination discovered a vesical calculus. Litholapaxy, October, 1888. Relief temporary. October 1889, patient debilitated; urine ammoniacal, loaded with pus and mucus. Retention. Examination failed to recognize any prostatic enlargement or to detect any stone or pathological change in the bladder. No kidney elements in urine. With the cystoscope a dark irregular spot about the size of a dime was seen on the left side of the *bas fond*. Slight induration recognized with end of cystoscope. This appearance was observed in subsequent examinations, and taken in connection with persistence of symptoms, seemed to warrant an exploratory operation. Operation, November 22d. A well marked enlargement of the third lobe of prostate recognized. The suspected point in the *bas fond* proved to be a vesical calculus which evidently had been encysted. This was removed. The question of removal of the enlarged third lobe was decided in the negative owing to the condition of the patient and the fact that he was passing a large amount of urine of low specific gravity. Recovery from operation satisfactory. Symptoms, however, soon returned. In January, 1890, the enlarged median lobe removed through a perineal section. The first step in the operation consisted of a suprapubic section, through which the bladder was explored and a phosphatic stone removed. An attack of subacute pleurisy rendered the condition of the patient critical and the convalescence tedious. About April 1st, he returned home cured, with the exception of slight vesical catarrh.

DR. H. G. MUDD showed a

FIBRO-MYOMA OF THE MALE PELVIS.

DR. J. W. WHITE said he felt inclined to continue the use of the rectal bag, notwithstanding its dangers. It gave a firm basis of support behind and made easier the recognition of small growths. He believed some of the risks would be diminished by using a cylindrically elongated bag.

DR. POST: He agreed with Dr. White that it was very difficult to know exactly in what cases of prostatic enlargement a portion of the prostate might be removed to give relief. There must be a number of cases in which we must be satisfied with some form of drainage, either through the perineum or over the pubes; and there must be a pretty large number of cases in which it was impossible to isolate a distinct growth which could be removed as such and how much to remove in cases of concentric hypertrophy or where it was impossible to make out a distinct lobe he felt uncertain; and it seemed to him it must require considerable experience yet to determine exactly the best course to pursue in each case.

DR. W. K. OTIS said that perhaps a better way of operating in suprapubic cystotomy was not to fill the bladder until after the wound had been made down to the bladder in order to obviate any danger of bursting the bladder from the patient's movements while being etherized. Where there was a very small bladder that held only five or six ounces, it seemed to him better to open it on a sound, lifting the bladder up through the wound so that one might examine it more easily than one could otherwise a small contracted bladder with a small amount of water in it.

DR. BANGS said he had become conservative with regard to the performance of prostatectomy. In cases in which he had done suprapubic lithotomy and found a very seriously obstructing prostate which could be easily removed and without much danger to the bladder, he had refrained, because he had observed that after the removal of a stone from a bladder which previously had been unable to spontaneously evacuate its contents, the bladder had recovered its function, so that the amount of residual urine would be slight and perfectly clear and limp. He thought elevation of the bladder by means of a moderately distended bag in the rectum did facilitate some steps in the operation and in old men especially, celerity of operation was very important. He had never found any especial advantage in draining the so-called prevesical space.

DR. CABOT thought there was great danger from the rectal bag, and that it was to be used with great care. There was this advantage in using it, that it brought into view the posterior wall of the bladder, where most of the tumors and morbid conditions were, and made much manipulation unnecessary. He thought the pear-shaped bag preferable to the sausage-shaped.

DR. BRYSON thought we must rely upon the general health, no matter what the technique of the operation, and the general health would be determined mainly by the condition of the kidneys. Suprapubic cystotomy in the young and vigorous was not, in his experience, attended with bad results. Heart-failure he feared more than anything else in these cases. He thought the observations of Dr. Belfield, in regard to the effect upon the arterial pressure of irritations about the rectum, vagina, etc., were of the highest importance.

DR. BELFIELD thought Dr. White need not censure

himself for the fatal result in his case. He himself had lost a patient under precisely the same circumstances, except that he had not removed a portion of the enlarged prostate. In his own case chloroform was used. As to the rectal bag, he meant that in the typical suprapubic cystotomy the bag was unnecessary, and should be omitted. There were cases in which the base of the bladder should be raised, and in those the bag was desirable. His conviction was that the advantage of suprapubic drainage, according to the method described by him, over what we used to call perineal drainage was enormous. Dr. Bangs had referred to a case in which spontaneous urination occurred after simple drainage. Inasmuch as the cause of the condition was to be found in enlargement of the prostate, in his judgment it would be better to remove that cause, particularly as in the ordinary case it would not add materially to the danger of the operation, and might prevent the return of the condition for which the operation was done. The condition of weakness, to which Dr. Bryson has referred, was unquestionably the chief factor to be feared.

DR. F. S. WATSON said statistics showed that the palliative operations were quite as dangerous as the radical ones, and when one had opened the bladder he might just as well go on and take out the growth, unless the case presented some peculiar difficulty, such as extreme exhaustion, in which event one would secure drainage and subsequently complete the operation. The device Dr. Otis mentioned of using a sound to lift up the bladder dated back to the early part of the century certainly. He was in accord with what Dr. Bryson had said in regard to the specific gravity of the urine. He thought the less the prevesical space was disturbed the better. Injection of both the rectum and the bladder, when it could be done, was, in his opinion, better than injection of the bladder alone. He did not think any drainage could be more thorough than that secured by the large-sized hard rubber tubes introduced by him two years ago.

A CASE OF CONGENITAL MALFORMATION OF THE URETHRA,

by DR. A. W. STEIN, New York.

The malformation in this case was, so far as Dr. Stein knew, unique. It consisted of an abrupt diminution of the canal about an inch anterior to the membranous portion. Urethra of normal calibre (33 F.) in front of the diaphragmatic obstruction; but here the mucous membrane was folded upon itself toward the lumen of the canal, and the urethra was reduced to about fifteen millimeters in circumference, and remained uniformly diminished to the vesical orifice, a distance of about three inches. As there was frequent micturition, and a history of gonorrhœa stricture was suspected, in exploring the urethra, the urethrotome was first used, then the bougie *a boule*, and subsequently smaller instruments. All met decided obstruction about five inches from the meatus, giving the impression that a very narrow stricture existed. Internal operations were abandoned, and external perineal urethrotomy without a guide contemplated. He was suffering from phthisis pulmonalis, and operative interference was deferred until he should become stronger. He died from asthenia in a few days. There was concentric hypertrophy of the walls of the bladder until its cavity was diminished to a capacity of about two ounces.

DR. J. B. WHITE mentioned a case of malformation of the urethra which had come under his observation. The testes were bound down on each side of the perineum in such a manner as to represent, on first inspection, the external genitals of the female. The penis was of the ordinary length and size for a child of two years, and there was no separation between the prepuce and the glans penis; no phimosis; no preputial opening, but the urethra opened just at the root of the penis between the two testes, and the penis gave much the appearance of an enlarged clitoris, and the other external genitals looked much like the external genitalia of the female.

DR. BRYSON stated, in connection with the general subject of stricture, that these were non-progressive cases. Whatever congenital malformation was there in the beginning remained the same throughout.

(To be continued.)

Recent Literature.

Cyclopaedia of the Diseases of Children, Medical and Surgical. Edited by JOHN M. KEATING, M.D. Volume III, 1371 pages. Philadelphia: J. B. Lippincott Co.

The third volume of this work comes at a most opportune time at the beginning of summer, containing as it does a large portion, — Part I., — devoted to the diseases of the digestive system, and one naturally turns at once to the article on "The Diarrhoeal Diseases, Acute and Chronic." This important subject is discussed in a thoroughly scientific manner by L. Emmett Holt in an article of one hundred pages, an article which, owing to the great strides made in this direction, differs widely from the chapters on this subject in text-books that have been published even a comparatively short time ago. The difficulty of classifying the cases coming under this head is admitted to be very great, and Dr. Holt has endeavored to avoid this, and to clear up the confusion on the subject, by separate pathological and clinical classification. His attempt is a step in the right direction, and forms, for the present at least, a good working basis. Although it is well-known that the word "diysentery" is very often misused in children's diseases, still one is hardly prepared to find it entirely discarded. That diarrhoeal diseases depend upon bacteria as their principal exciting cause is thoroughly accepted by the writer, who bases his argument partly on the etiology of these diseases, partly on their clinical history and pathology, and partly on analogy.

The chapter on pathological anatomy is formed almost entirely from a study of 109 autopsies, and is illustrated by excellent plates showing the intestinal lesions as seen with the naked eye and by means of microscopic sections. The chapters on treatment should be read with great care, as they are most excellent; but, as Dr. Holt says, "Those who consult these articles to find formulae will be disappointed. . . . The routine use of certain complicated formulae because some writer has lauded them as 'good for diarrhoea,' cannot be too much condemned." The dietetic part of the treatment is of course very prominent, and the starvation plan for the first hours is especially recommended. The old-fashioned astringents are dis-

carded, and the limitations in the use of antiseptic drugs shown.

A very interesting and suggestive chapter is presented by Wm. D. Booker, on the "Intestinal Bacteria of Children," in which he says: "As far as the biological characters of the bacteria in the diarrhoeal stools of infants have been studied, it appears that not one specific kind, but many different kinds of bacteria are concerned, and their action is manifested more in the alteration of the food and intestinal contents, and in the production of injurious products, than in a direct irritation upon the intestinal wall."

EARL, of Chicago, contributes a useful article on "Constipation," a subject which, notwithstanding its frequency, is not generally dwelt on in treatises on children's diseases.

In a work so well illustrated we are surprised to find no plates or even figures of the intestinal worms, in the brief chapter devoted to the subject.

Among the other valuable papers in Part I., are "Functional Disorders of the Stomach," by Pepper; "Peritonitis," by Ashby; "Congenital Abnormalities of the Intestine," by Wharton; and some eighty-five pages on Diseases of the Liver, by Chapin, Musser and Hatfield. Musser gives a table of thirty-four cases of abscess of the liver in children.

Part II., "Diseases of the Genito-urinary Organs," contains over two hundred pages of interesting matter by Tyson, Goodhart, Jacobi, Sturges, Keating and others, on the various divisions, many of the articles being profusely illustrated and exhaustively written. The paper on "Acute and Chronic Bright's Disease," by Goodhart, is particularly valuable, the writer pointing out very clearly the peculiarities of this disease in children as distinguished from that in the adult.

Griffith writes an extensive treatise on "Diseases of the Blood," unavoidably omitted from its proper place in Volume I. The methods for examination of the blood are thoroughly explained, and the article is illustrated by colored plates and by cuts.

The last five hundred pages are devoted to "Surgery" and "Diseases of the Osseous System and Joints." A criticism might be made here that some of these articles, — notably that on "Wounds," by McCann, and "Amputations," by Hopkins, — might with advantage be much abbreviated by limiting them to the consideration of the subject as it concerns children alone. This criticism does not, of course, apply to such articles as those on "Club-Foot" and "Torticollis," by Bradford and Brackett; on "Lateral and Functional Curvatures of the Spine," by Gibney; on "Deformities of Bone," by Gerster; on Pott's Disease," by Roberts; and on "Mechanical Treatment of Deformities of Infantile Paralysis," by Brackett. It is impossible in this limited space even to mention all of these articles. They are carefully written and well illustrated, many of the illustrations being from photographs.

This volume, like its predecessors, is thoroughly indexed, and is certainly a satisfactory work of reference.

C. W. T.

An Experimental Study in the Domain of Hypnotism.

By D. R. VON KRAFT-EBING, Professor of Psychiatry and Nervous Diseases in the Royal University of Graz, Austria. Translated from the German by CHARLES G. CRADDOCK, M.D., Assistant Physician Northern Michigan Asylum. Octavo, pp. xii,

129. New York and London: G. P. Putnam's Sons. 1889.

This little monograph by one of the greatest alienists in Germany has already become classical; and amid the mass of rubbish written on hypnotism by incompetent observers, it stands as one of the few exhaustive scientific studies. It is with pleasure, therefore, that we greet the work in a form accessible to the English reader. In October, 1887, Kraft-Ebing had the opportunity, which is so infrequent, of studying the manifestations of hypnotism in a peculiarly favorable subject. The patient was a young woman of twenty-nine, an hystero-epileptic of a pronounced type, who had for many years been the victim of repeated hypnotizations. As a consequence, her consciousness was never entirely clear, but fluctuated between complete and partial unconsciousness. She had typical hystero-epilepsy, right hemianesthesia and sexual perversion. In consequence of her unbalanced state, she had committed various acts, some of which had brought her into the hands of the police, who transferred her to the medical authorities at Graz. There, in her normal lucid state, she was found to present the ordinary picture of grand hysteria. It was very easy to hypnotize her; and in this state the only avenues of suggestion were the sensory and auditory, the cortex being in a state of great inhibition, to the exclusion of spontaneous apperception. Through suggestion in these channels, however, the experimenter could unlock any portion of the cortex desired, with unlimited power. By this means a therapeutic action was attempted, with some benefit. Unfortunately, however, an hystero-epileptic attack, or voluntary effort on the part of the patient, produced a third auto-hypnotic state. This state was found divisible into three, which could be experimentally produced, and in them, among other manifestations the patient unconsciously stole bright objects. Inhibition was less than in the second state; but the attempt to carry out a post-hypnotic action commanded in this state, if it involved a state or a complicated action, threw the patient into a state of auto-hypnotism. These three spheres of consciousness never intersected. In the first the patient was an hystero-epileptic, with clear consciousness; in the second she was in a state of great inhibition, but could be impelled to automatic action; in the third she was a somnambulist, capable of spontaneous action within a limited sphere as a result of auto-suggestion or post-hypnotic suggestion by a third person, but depending on a dreamily deepened consciousness. In this state she became a thief, and could be made the involuntary instrument of crime.

We must refer the reader to the original for the details of this study, the most valuable and thorough inquiry into hypnotic phenomena that has yet appeared. Kraft-Ebing recognizes the value of suggestion in the treatment of functional nervous affections, but the case shows most strikingly the dangers of hypnotism in unskilled hands, — dangers which many enthusiasts seem disposed to slight.

P. C. K.

— A doctor in Philadelphia has been arraigned on the charge (to which he pleaded guilty) of having sent a letter to a delinquent patient in an envelope on which was printed, "Dead-Beat, Bad-Debt Collection Agency." The fine was one dollar and costs. One more case where the truth must not always be spoken!

RECENT SPECULATIONS AS TO THE NATURE OF CANCER. THE ELECTROLYTIC TREATMENT OF CANCER.

DR. J. INGLIS PARSONS, of the Chelsea Hospital for Women, has published his views of the nature of cancer, and the results of the treatment by a new electrolytic process of several well-marked cases that were considered as unsuitable for operation. His paper has appeared in several of the British medical journals, and has been reprinted in *Wood's Medical and Surgical Monographs* for March, 1890. Of the various hypotheses to explain the nature of cancer, that theory which has found its most elaborate expression in the Morton lecture of 1889 by Dr. John Marshall, although Dr. Parsons claims priority of statement, is that cancer is due to an escape of healthy cells from the control of the nervous system. Dr. Parsons asks whether it is not possible that all tumors are, in the first instance, composed of cells formed in the normal process of repair, but that, having escaped from the control of the nervous system, they take on an independent life, and continue to proliferate and develop without check, just as all living cells are capable of doing *ad infinitum* under favorable conditions? The frequent association of cancer with a depressed condition of the nervous system and with local causes of injury, is explained by this hypothesis. According to Dr. Gross's statistics, out of 907 cases of cancer of the breast, there had been antecedent inflammation in 20 per cent., and a history of injury in 13 per cent. Dr. John Williams found microscopical evidence of the gradual transition from healthy tissue into cancer in a case described by him in the Harveian lectures.¹

Dr. John Marshall, in the lecture above alluded to,² insists on the lack of demonstration that in the epithelioid cells of cancer there are any nerve fibres; consequently, their growth and behavior are unregulated, disordered and anarchical. Even in plants there is "a fine, delicate, protoplasmic fibre" which seems to govern the evolution of the outgrowing cells of the

¹ Lancet, November 30, 1889, p. 1108.

² Lancet, November 23, 1889.

plant. In the animal, nerve filaments penetrate into all normal epithelial tissues; "it has been, moreover, demonstrated that a nerve, a commanding thread, an electric cord, as it were, passes into each individual cell, and what can be assigned as a function to it, except that it is the governing cord, the co-ordinating fibre of its life?"

Dr. Marshall does not believe "that in the pell-mell agglomeration which we see in a cancer, each cell has its own proper guiding fibre." In answer to the question how the nerve connection comes to be severed? he thinks that it may be from the extreme rapidity of the cell growth. In the healthy formation of epithelial tissue, the nerve tissue would still remain in it; but in the overgrowth excited by some injury, "the cells break away from the nerves; they retain the power of multiplication within themselves, because each cell, like the cell of a minute infusorial creature, contains the quantity and kind of material which is necessary to build it up, but it does not retain the governing tissue with its power of control."

We have not time to enter into the further explanations based on the supposed chemistry of the cancer-cell, which form an interesting part of Dr. Marshall's lecture. Dr. Parsons also insists on the severance of nerve connection, and on the consequent proliferation of the cancer-cells, resulting from their independent existence, "which enables them to overcome the healthy cells, since these, for want of sufficient stimulus, remain passive." But the malignant cells multiply with such prodigality that they soon suffer in their nutrition, and their vitality is lowered; and this very fact causes them to perish more readily than the healthy tissues.

Dr. Parsons has experimentally attempted the destruction of cancerous growths with both the interrupted and the constant voltaic current. He has found the constant current worthless to check the growth of cancer, while from the interrupted galvanic current, some most gratifying results have been obtained. The *modus operandi* is as follows: The patient is anaesthetized, the current is then passed through the tumor and all the tissues for some inches around it by means of fine insulated needles, so as not to injure the skin. A battery of seventy cells, with an electro-motive force of 105 volts, is used; the intensity of the current to commence with is ten milliampères, gradually increased to 600 milliampères, and gradually flashed through the growth in every direction from fifty to one hundred times, according to circumstances. The pulse and respiration are carefully watched. The effects produced by the action of the electricity consist in a cessation of growth, gradual disappearance of pain, some shrinking and hardening of the tumor and enlarged glands, followed by improved nutrition and a better state of the general health. The growth, as a whole, does not disappear, but remains as an inert mass, composed, in all probability, of fibrous tissue alone.

The advantages claimed for this method of treatment are as follows:

(1) There is no destruction to the normal tissues of the body, and if recurrence should at any time occur, its progress can be immediately stopped, and the treatment repeated as many times as necessary. Life would by this means be prolonged indefinitely, provided that metastatic deposits had not occurred before the commencement of the treatment.

(2) Patients are not obliged to keep their beds for more than a day or two, as a rule. They lose no blood, and are not generally any weaker.

(3) The current can be passed through almost any part of the body, and thus arrest growths which could not by any possibility be otherwise treated.

The above may be regarded as the latest phase of the question of the electrolytic treatment of cancers. It is for the electro-therapeutists to judge as to the merits of this method. It is notorious that constant currents of considerable intensity have failed to arrest or destroy cancerous growths, though often effectual in the case of fibroid tumors. Dr. Parsons thinks that he has demonstrated that the interrupted voltaic currents may, under careful management, be used with safety, while their destructive effect on the cancer-cells is considerable; to quote his own language: "the impact of a powerful current, when suddenly flashed through, causes death to those tumor-cells which lie in the nearest path between the poles where the lines of force are most concentrated, or else they are sufficiently injured to lead to their gradual atrophy."

A WORD TO YOUNG PRACTITIONERS ON "CHANGING DOCTORS."

It is not intended to give to young men just starting in practice any lengthy advice — of that they have probably received their full share, all they care for, and more than they will heed; but there is one subject on which a word may not be amiss.

It is inevitable that they should see patients whom they would prefer to keep, leave them for some other practitioner. It is a common experience, and unavoidable. In a large city it is a matter of little consequence: in a country town it is more serious, and often causes very bitter feelings. But no man ever gains anything by being angry over it. It is much better to recognize the fact that it must occasionally happen, and to accept it gracefully. If a family is determined to change, it has the right to do so. If the doctor is angry and shows it, he makes it impossible for them to return to him later if they should, at some future time, realize that the change was a mistake.

The fact will remain that no one physician can render satisfactory service to everybody. Human nature is too diverse in its various forms for any one practitioner to give universal satisfaction; and it is well that it is so, or all practice would gravitate toward that one.

Nothing that has been said is intended to lessen the efforts of every practitioner to act honestly by every case that falls into his hands, but simply to induce in

the minds of younger members of the profession a philosophical spirit which will prevent the loss of a desirable patient from destroying their peace of mind.

MEDICAL NOTES.

— Up to June 25th there had been a total of one hundred and ninety-six cases of cholera in Valencia, of which one hundred and thirteen proved fatal. Such violence of the disease shows that it is of a malignant type.

— The bill providing for three separate boards of State medical examiners in New York State after September 1, 1891, to be appointed by the regents of the university — one board to represent the medical society of the State of New York; one to represent the homeopathic medical society of the State of New York; and one to represent the eclectic medical society of the State of New York — has been signed by Governor Hill, and is now the law of the State.

— The Faculty of the Jefferson Medical College, Philadelphia, have contemplated the enlargement of their building for over two years. About one year ago they secured several properties fronting on Walnut Street, west of Tenth, for this purpose. It is now stated that the proposed improvements will be made within the next six months. The addition, when finished, will be used for class-rooms, operating-rooms, clinics and library.

— Medical students in London have been compelled to go through a course of four years' study, hospital attendance and lectures before being qualified to appear for the final examination. By an order of the General Medical Council of England, issued last month, the term of preparation has been extended to five years.

The Raleigh, N. C., *Chronicle* is one paper which has an appreciation of the medical profession. Speaking of the late meeting of the State Society, it says: "There is no profession in the State that stands higher — and deservedly so — than the medical profession. Learned, kind, sympathetic, benevolent, they are an honor to the commonwealth, and deserving of all the esteem and love that an affectionate and grateful people can show to the best product of their civilization."

— The *Medical News* says that on May 26th the Bicêtre, the great Parisian asylum for the insane witnessed the strange sight of a rebellion of its inmates. The rebellion was begun by a maniacal patient bursting the bars of his cell and then releasing forty others. They attacked and drove back their guards, and then proceeded to ransack the quarters of the keepers, after which they kept up the fight quite fiercely until the guards got access to the water-hose and turned it on them; this frightened and cowed the rebels so that they retreated and were one by one returned to their cells.

— A contemporary calls attention to the growth of the "naphtha habit" among the female employees of rubber factories. The inhalation of naphtha fumes produces a peculiarly agreeable inebriation. Naphtha is used to clean rubber; and is kept in large boilers, to the valve of which the employees obtain access and breath the fumes. The habit was introduced from Germany, and is chiefly found in New England.

— We clip the following sentences from Mr. Lawson Tait's recent address on "The Details of Abdominal Section," before the Cardiff Medical Society: "It is the nidus for germs that is to be feared, and not the germs themselves, and your every care should be to have nothing about that could serve as a soil for their growth and development. I use plain water, no kind of chemical compound. . . . I never allow nurses to wear watches with second hands, but I give them a little sand-glass which runs for a minute, so that there is no margin for error. I take the temperature in centigrade, so that the friends of the patient may not understand it."

— It appears that in China the distinction between the physician and the surgeon is somewhat sharply drawn, as appears from the following story told by the writer:

"An English tourist was riding a bicycle in Hong Kong, when he fell from his bicycle with such violence that one of the wire spokes was run into his shoulder, where it broke off and stuck fast. The man was removed to a house and a surgeon summoned. The surgeon first demanded his fee. After pocketing his money he broke off the protruding point of the spoke, leaving the other fragment imbedded in the sufferer's body. He then went away. The tourist was in intense agony, but the surgeon would not help him. Medical etiquette forbade. 'The case is for the physician,' he said, 'as the wire is inside the body.'"

— A curious fraud has been detected in Milwaukee, where a warrant was issued authorizing the arrest of Joseph A. Wilt, Dr. C. A. Jansen and Jim Lee, alias Gun Wa, on a complaint sworn out by a city detective, charging them with conspiracy to defraud, obtaining money under false pretenses, unlawful assumption of the title of "doctor," violation of the pharmacy statute and circulation of obscene literature. Gun Wa is an alleged Chinese physician and graduate of several Chinese medical colleges, who professes to cure all diseases known to man. Wilt is his manager and Dr. Jansen interpreter. Their office was established in July last and has done an enormous business. Wilt acted as manager and interpreter until March last, when the increase of business was such that it was found necessary to procure help and Dr. Jansen was brought on from Chicago to act as interpreter. An investigation was set afoot and it was found that the alleged doctor was a Chinese laundryman sent on from Denver by Frank L. Smith, head of the Gun Wa company, which has branches in Denver, Kansas City, Detroit, Indianapolis and Milwaukee, and that

neither Wilt nor Jansen, who acted as interpreters, could speak a word of Chinese. Since opening the office here a year ago three Chinamen have played the part of Gun Wa.

NEW ENGLAND.

— A considerable number of cases of typhoid fever has recently appeared in Waterbury, Conn., and the Board of Health has forbidden the further use of the milk of a neighboring dairy, among the patrons of which a disproportionate prevalence of the disease is said to have occurred.

Miscellan.

ACUTE OEDEMA GLOTTIDIS AFTER POTASSIUM IODIDE.

CASES of this nature are few in number, and one reported by Dr. Groenouw is quoted in the *Practitioner*, for June, from *Therapeut. Monatschete*, No. 3, 1890. "A strong, healthy man, forty-three years of age, suffering from optic atrophy, and with the urine quite free from albumen and sugar, was treated with iodide of potassium, in the form of a watery solution, in doses of seven to fifteen grains thrice daily. On the afternoon of the second day, when he had taken about forty grains of the salt, he complained of a feeling of rawness in the throat; by the evening of the fourth day there was hoarseness, with pain on swallowing, localized in the right side of the larynx. These symptoms, which were not by any means prominent, were not more pronounced on the evening of the sixth day, after the use of a little over three drachms of iodide. The same night, after two hours' quiet sleep, the patient awoke, began to cough, and noticed suddenly, that although the expiration was free, the inspiration was difficult, and he felt as if a valve were in the throat. The difficulty lessened in the space of two hours, and he slept again, the dyspnea having quite disappeared by next morning. In the afternoon, on examination, the right ventricular band was edematous, as also the mucous membrane over the arytenoid cartilage and the ary-epiglottic ligament. After an intermission of two days, the iodide was resumed; and although the dose was a full one, no further symptoms of iodism appeared. In spite of the severity of the attack tolerance was established. The iodide of potassium given was exactly the same as other patients were using, and it is not likely that the symptoms were due to impurity of the drug. Groenouw observed a similar case two years ago in a woman of sixty-six, who was the subject of a moderately enlarged thyroid, but without difficulty of breathing, and was suffering from oculo-motor palsy of one eye, for which iodide of potassium was prescribed in small doses. After seven grains, severe coryza and conjunctivitis, with great dyspnea and loss of voice, came on. Examination showed marked pharyngeal catarrh and evident swelling and redness of the ventricular bands. Three days later, when the symptoms had subsided, four grains were given daily for three days; but, on being increased to twice daily, there appeared — more or less every time — hoarseness, difficulty of swallowing and pain in the head. The drug was accordingly stopped for four days, and then the patient took about four grains daily, diluted with

much water, the dose being gradually increased in the course of the next two weeks to fifteen grains a day. On attaining this amount, it had to be reduced on account of pain in the throat and general restlessness; and seven days later it was discontinued altogether. Groenouw thinks the following conclusions may be drawn: After the administration of iodide of potassium, there occurs in certain rare cases great dyspnea due to oedema of the glottis, sometimes so extreme as to demand rapid tracheotomy. It does not arise from long use or large doses — relatively small amounts have hitherto induced it; and other symptoms of iodism, such as headache, are wanting. The action is local upon the larynx, not part of the general oedema. Its cause is certainly the iodine, not the potassium, and it cannot be ascribed to any impurity. No local or general diseased state, for instance, cardiac or renal disease, can be recognized; and the cause must be looked for, rather in an idiosyncrasy of the individual, although even this is not by any means absolute, as a complete tolerance may be established after a few days' pause."

SOME CONSERVATIVE VIEWS OF HYPNOTISM.

In the discussion on this subject, which has, of late, been carried on, there have not been wanting those who protest against the recognition of hypnotism as a therapeutic agency, particularly from its dangers if abused as it is so likely to be. The lawyers have been turning their attention to it and recognize that its possibilities for crime are great. Among medical opinions we insert two, first that of Dr. E. C. Spitzka, the president of the American Neurological Association, who says:

"I find it difficult to discuss the matter with patience. That the phenomena of hypnotism exist and that they command the earnest investigation of scientific men there is no doubt. But I do not believe the time has come to use the method as a remedial agent. We don't know enough about it. I am sorry to say I cannot draw a sharp line between some of the phenomena of hypnotism and the ideas of the spiritualists and old-fashioned mesmerists. The charlatans who use the system to humbug the public are frauds who should be suppressed. Did you ever see a collection of photographs of those people? The rogues' gallery would be a collection of gentlemen compared with them. And yet they undoubtedly have a mysterious power over certain persons. Animal magnetism won't account for it. I saw the other day the daughter of a New York physician, a delicate, beautiful young girl, completely hypnotized by one of the ugliest, most repulsive-looking Russians you ever saw."

Again, Sir Andrew Clark says, in the *Lancet*:

"The first thing that strikes me in connection with hypnotism is the confidence with which it is asserted that it has been proved beyond dispute to be so successful that it cannot drop. But I am old enough to remember that this was said in the time of mesmerism. Practically, mesmerism fell into desuetude fifteen years ago. Except in distant corners such a thing is scarcely heard of. Now, from some researches which have been conducted at Nancy and stimulated by the opposition of the Salpêtrière school, we have the subject once more brought before us, and we are told of the advent of a great and important practical truth. Therefore we are told that hypnotism has established itself

for all good. I have no hesitation in prophesying that before twenty-five years have passed it will be in the same position that it was twenty-five years ago."

Correspondence.

[From our Special Correspondent.]

PARIS LETTER.

DR. PÉAN.

PARIS, JUNE 6, 1890.

MR. EDITOR:—The subject of this note is about sixty years of age, and more than twenty years ago he obtained the world-wide reputation of being a skilful surgeon and a brilliant operator. Those who have visited the Hôpital St. Louis, of which he is surgeon, have greatly appreciated his merits as an operative surgeon. He has often been compared to Ferguson for general surgery, and to Sir Spencer Wells and to Lawson Tait for abdominal surgery, in which branch he has excelled. Saturday is his day for operations at the hospital, when a great number of foreign surgeons may be met there. Every Saturday he performs, between 10 and 12 o'clock, five or six operations, among which are always several of considerable importance. He delivers, at the same time, clinical lectures on the cases on which he is about to operate. The scene in the operating theatre is striking and characteristic. He is a man of powerful build, with black hair and whiskers, his face shows intelligence and determination, and his whole appearance indicates a man of superior knowledge and great courage. While energetic in manner, he is cool and self-possessed. He is in the habit of describing always beforehand, as most French surgeons do, the leading features of each case on which he is about to operate, and the precise method which he intends to adopt. While operating, he describes each modification of his methods which the circumstances call for, and clearly demonstrates not only his manual of proceeding at each stage, but the reasons which dictated it, and the changes which he introduces to suit the peculiarities of the case as it develops itself under the knife.

What attracts the attention of visitors is the display of numerous instruments, and the number of large and small haemostatic forceps, which he has adopted in preference to any other method of arresting hemorrhage. He has for a long time almost completely abandoned ligatures, relying on the use of preventive compression by small and large haemostatic forceps, of which he makes the freest use. By this means he succeeds in greatly abridging the time occupied in operation, and in arresting the flow of blood, which is otherwise apt to obscure the view of the parts in course of operation both from the surgeon and the spectator. He claims that the free use of his haemostatic forceps gives much greater certainty to the proceedings of the operator. Dr. Péan performs more than five hundred operations every year in this hospital, exclusive of the operations performed by him in private, "*maisons de santé*," with very encouraging results. Those for the past year, for example, have been so successful that he has not had one single death due directly to the operation.

As a general surgeon Dr. Péan may find his equal among the younger surgeons of the day, but for abdominal surgery, and particularly ovariotomy, he has certainly not been surpassed. Among the most important of his modifications of ordinary operative proceedings is that which he describes as "*le morcellement*," or removal of tumors in sections, by proceeding from the centre to the outer circumference. Piecemeal enucleation, "*morcelement de tumeurs*," and compression of vessels by haemostatic forceps left *in situ*, combine considerably to abridge the time occupied in operation, and avoid many operative complications. This proceeding has been described and illustrated by the author in *La Gazette des Hôpitaux* in 1872 and in 1887, and also in the seventh volume of his "*Leçons de Clinique Chirurgicale*." The method consists

especially in operating from the centre to the periphery, so that the surgeon reaches the great vessels and the important organs, which are generally on the external surface of the tumor, only when the operation is drawing to an end. This is especially a consideration of much interest when dealing with tumors which occupy a dangerous region. Many tumors which are considered almost beyond the range of operation in such regions, especially when very large, have come easily within the reach of the knife by this method. Thus, the ablation of voluminous tumors of the neck, of the thyroid gland, face, abdomen and pelvis, is carried out with great rapidity and facility, and with very little loss of blood with the aid of forcipressure.

For the piecemeal enucleation of soft tumors and of tumors of the bones, M. Péan employs special cutting-forceps,—"pince *emporte-pièce*"—which easily remove masses of the substances dealt with. For operations on the bones, he has for nearly twenty years employed an instrument constructed by Mathieu, the well-known surgical instrument maker, called the polytritome, which he considers of the first importance. By the aid of this instrument trephining and sections of the bone can be rapidly carried on, and it also allows the operator subsequently to remove portions in pieces as he desires. For the skull, for example, instead of trephining with one crown of the trephine, it is enabled, with the polytritome, to employ five or six circles of the trépan, and with his *pince emporte-pièce* he removes all the intervening portion as quickly as if he were operating on the soft parts. For the maxillary bone, without looking for the special landmarks, which are carefully sought out in order to introduce the chain-saw, M. Péan simply makes a preliminary incision, removes the maxillary bone by *morcelement*, beginning at the centre, and in ten minutes he arrives at the periphery and completes the operation. So, also, for the ribs,—in lieu of cutting the rib, he takes the *emporte-pièce*, removes the rib in pieces after having detached the periosteum, without troubling himself about the neighboring organs. In the same way he has removed without difficulty, with the polytritome and the *emporte-pièce*, enormous enechondromata, which projected into the pleura and partly filled it, or into the ilium. Whenever he has to deal with a bony tumor, he attacks it similarly from the centre, so that he never has any fear lest he should injure the viscera in the neighborhood of the operation.

The substitution of the haemostatic forceps for the common ligature is now pretty generally adopted by the French surgeons. For instance, in vaginal hysterectomy they have substituted for ligature of the broad ligaments the application of long curved forceps for continuous pressure on the folds of the membrane, these forceps being intended to insure haemostasis, and left *in situ* for twenty-four or forty-eight hours. This practice, due to Dr. Péan and Dr. Richelot, is considered to have considerably simplified the manual proceeding in an operation, on the value of which opinions are, however, divided. Dr. Péan applies this method of forcipressure to the treatment of aneurisms of the limbs. In this method compression replaces the ligature. According to the author, the seats of aneurisms cause considerable differences in the latter. An aneurism of the hand has no gravity whatever; a femoral or a popliteal aneurism is a serious lesion. If it concerns a diffuse aneurism of the hand or of the foot, the forceps should be placed above and below the aneurism. If the aneurism is circumscribed, the sac should be removed after having compressed the artery. Antiseptic dressing, compression and immobility complete the cure. If one has to do with a diffuse aneurism of the popliteus, the popliteal artery should be compressed above and below the sac, as also all the collateral branches. The forceps should be left *in situ* for thirty-six or forty-eight hours. If secondary hemorrhage should be produced, the ends of the arteries should be taken up and compressed. The author considers this method of compression superior to the ligature. It is more prompt, arteries are less liable to be injured than with the ligature, which denudes the arterial surface to a certain extent, thus producing the tearing of the *vasa vasorum*.

Dr. Péan's achievements in surgery are most remarkable, and many of them prove the great advantage of surgical interference in what may be termed strictly medical cases. He has within the last few years successfully removed about twenty tumors affecting the brain or its coverings, in patients, however, in whom there were physical signs which pointed to the seat of such tumor. He is an untiring worker. Endowed with a vigorous body and an active brain, he finds no pleasure in rest. His voluminous works testify to his zeal and fertility as a writer, and the clinical material they embody shows an amount of personal experience seldom acquired by a man of his age. He has invented a variety of operative proceedings and of instruments, of which a description is to be found in the volumes of clinical lectures which he publishes every two years.

As one of the most remarkable achievements in surgery due to Dr. Péan is the total ablation of the bones of the face, a note on which he communicated to the Academy of Medicine on January 14, 1890. The case was that of a

woman aged thirty-two years, who was the subject of multiple tumors of the bones of the face, in which the sphenoid, the three maxillary and the malar bones were affected by osteo-fibromata consecutive to dental heterotopies. The operation was most successful; and in conjunction with Mr. J. P. Michaels, a dentist, who undertook the prosthetic part, it reflects the greatest credit on both surgeon and dentist, not only in an aesthetic point of view, but the functions of the mouth, throat and nose have been restored to almost their normal condition.

Notwithstanding the preeminent qualities possessed by Dr. Péan, he was, for reasons best known to the members of the Academy of Medicine, not received among them till about two years ago, although he had more than once presented himself as a candidate. Some attribute this circumstance to professional jealousy, others say that, although he is a first-rate surgeon, he was not considered sufficiently a savant to have the portals of the Academy opened to him.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 21, 1890.

Cities.	Estimated Population for 1890.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3,275; under five years of age 1,546: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 827, consumption 331, acute lung diseases 260, diarrhoeal diseases 549, diphtheria and croup 104, typhoid fever 67, scarlet fever 31, measles 25, cerebro-spinal meningitis 23, malarial fever 22, whooping-cough 21, erysipelas 8.

From scarlet fever New York 11, Brooklyn 5, Chicago 4, St. Louis 1, Cincinnati 1, Philadelphia and Worcester 2 each, Baltimore 1. From measles New York 10, Philadelphia and Brooklyn 3 each, Chicago, Baltimore and New Orleans 2 each, Washington, Charleston and Lawrence 1 each. From cerebro-spinal meningitis Washington 5, Chicago and St. Louis 4 each, Brooklyn and Cincinnati 2 each, Philadelphia, Boston, Worcester, New Haven 1 each. From malarial fever New Orleans 9, Brooklyn 3, New York and Baltimore 3 each, Philadelphia and Charleston 1 each. From whooping-cough,

New York 8, Philadelphia, Brooklyn, St. Louis and Charleston 2 each, Chicago, Boston, Portland, Lowell, and Salem 1 each.

From erysipelas New York 4, Chicago 2, Brooklyn and Lawrence 1 each. From puerperal fever Philadelphia, Brooklyn, Washington and Lowell 1 each.

In the two largest greater towns of England and Wales with an estimated population of 9,715,599, for the week ending June 14th, the death-rate was 17.2: deaths reported 3,199: Infants under 1 year 684, acute diseases of the respiratory organs (London) 240, measles 148, whooping-cough 93, scarlet fever 51, diarrhoea 39, fever 36, diphtheria 33, small-pox (Plymouth) 1.

The death-rates ranged from 9.6 in Nottingham to 26.2 in Manchester: Birmingham 17.2, Bradford 17.1, Hull 15.1, Leeds 17.9, Leicester 13.2, Liverpool 20.7, London 16.2, Norwich 14.2, Portsmouth 19.3, Sheffield 21.0, Sunderland 19.5, Wolverhampton 22.5.

In Edinburgh 16.1, Glasgow 25.5, Dublin 25.3.

The meteorological record for the week ending June 21, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.			Relative Humidity.		Direction of Wind.		Velocity of Wind.		State of Weather.*		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 12, 1890, TO JUNE 27, 1890.

By direction of the Secretary of War, leave of absence for three months and fifteen days, to take effect as soon as his services can be spared, is granted Captain WILLIAM C. BORDEN, assistant surgeon. Par. 1, S. O. 143, A. G. O., June 23, 1890.

Captain HOWARD CULBERTSON (Retired) died June 18, 1890, at Zanesville, Ohio.

APPOINTMENTS.

To be Assistant Surgeons with the rank of First Lieutenant: FRANCIS R. KEEFER, of Pennsylvania, June 26, 1890, vice Woodward, promoted.

THOMAS U. RAYMOND, of Indiana, June 6, 1890, vice Newton, resigned.

HENRY D. SNYDER, of Pennsylvania, June 6, 1890, vice Wilson, resigned.

ALLEN M. SMITH, of New York, June 6, 1890, vice Matthews, promoted.

ASHTON B. HEYL, of Pennsylvania, June 6, 1890, vice Hall, promoted.

JOSEPH T. CLARKE, of New York, June 6, 1890, vice Porter, resigned.

By direction of the Secretary of War, Major CHARLES R. GREENLEAF, surgeon, will attend the encampment of the Pennsylvania National Guards, at Mount Gretna, Pennsylvania, from the 18th to the 26th of July, 1890, for the purpose of accompanying the surgeon-general of Pennsylvania in his inspection of the camp. Par. II, S. O. 144, A. G. O., June 20, 1890.

Leave of absence for one month, on surgeon's certificate of disability, is hereby granted Captain MARCUS E. TAYLOR, assistant surgeon, with permission to go beyond the limits of this division, and to apply for an extension of five months. Par. I, S. O. 43, Division of the Pacific, San Francisco, Calif., June 13, 1890.

By direction of the Secretary of War, Major SAMUEL M. HOOTON, surgeon, U. S. Army, will visit the encampment of the Maine Volunteer Militia, at Augusta, Me., during the period of its encampment, June 30, to July 4, 1890, inclusive, for the purpose of instructing the medical department thereof in its duties in camp, and on completion of this duty will return to his proper station. S. O. 143, paragraph 5, Adjutant-General's office, Washington, D. C., June 19, 1890.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING JUNE 21, 1890.

GASSAWAY, J. M., surgeon. When relieved at Cairo, Ill., to proceed to New Orleans, La., and assume command of the service at that station. June 4, 1890.

STONER, G. W., surgeon. Granted leave of absence for three days. June 18, 1890.

WASDIN, EUGENE, past assistant surgeon. Granted leave of absence for fourteen days. June 5 and 10, 1890.

WHITE, J. H., past assistant surgeon. To proceed to Savannah, Ga., on special duty. June 8, 1890.

HEATH, F. C., assistant surgeon. Granted leave of absence for fifty-eight days. June 10, 1890.

MAGRUDER, G. M., assistant surgeon. Granted leave of

absence for twenty days. June 2, 1890. Ordered to examination for promotion June 5, 1890.

WOODWARD, R. M., assistant surgeon. Relieved from duty at Chicago, Ill., to assume command of service at Cairo, Ill., June 4, 1890.

CONDICT, A. W., assistant surgeon. Upon expiration of leave of absence to report to medical officer in command at Chicago, Ill., for duty. June 4, 1890.

RESIGNATION.

HEATH, F. C., assistant surgeon. Resignation accepted by the President, to take effect August 31, 1890. June 10, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 28, 1890.

PAGE, JOHN E., Berryville, Va.

KENNEDY, ROBERT M., Berryville, Pa.

WHITEFIELD, JAMES M., Richmond, Va.

STONE, LEWIS H., Litchfield, Conn.

have been commissioned assistant surgeons in the Navy.

ATLEE, LOUIS W., assistant surgeon, detached from the U. S. S. "Marion," and granted three months' leave.

OBITUARY. HOWARD CULBERTSON, M.D.

Dr. Howard Culbertson, of Zanesville, O., died June 18th, after a week's illness, from results of acute dysentery contracted in the army. He was born in Zanesville in 1835. In 1858 he graduated from Jefferson Medical College, Philadelphia. At the beginning of the Civil War he offered his services to the Union, and in 1862 was appointed surgeon of Ohio Volunteers, and was brevetted lieutenant-colonel in 1865. On February 28, 1865, he was appointed a surgeon of the United States Army, and remained in the service until January 8, 1869, when he was retired on account of disability contracted in the line of duty. He was the author of several works on medicine and surgery, the one "Excision of the Larger Joints of the Extremities," being recognized as a standard authority both in America and Europe. In 1870-77, he was professor of ophthalmology in the Columbus Medical College, and at the time of his death he was assistant editor of the *American Journal of Ophthalmology*, published at St. Louis.

Lecture.**INFLUENZA IN MASSACHUSETTS.¹**

BY GEORGE R. SHATTUCK, M.D., OF BOSTON.

MR. PRESIDENT AND FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY: As you well know the time-honored Annual Discourse takes place as usual to-morrow, on the last day of this meeting, just before the annual dinner, and is unquestionably looked forward to this year with all of the usual interest. That an additional claim should be made upon your time and attention this evening is an innovation, and as such requires some words of explanation.

At the annual meeting of the Society in the year 1858 the treasurer reported that, "the Society has come into the enjoyment of the Shattuck legacy, amounting to \$9,166.87, the income from which will contribute largely towards meeting the expenses of publication to which it is especially designated." Since that time this fund has remained with the Massachusetts Hospital Life Insurance Company, invested in one of that company's annuity policies, and has yielded interest varying from 8.25% in 1866, and during the period of inflation just after the war, which was the highest rate, to 4% which has been the rate annually during the last ten years. It appears from the treasurer's accounts, as your present treasurer kindly informs me, that until 1872 the income was expended for printing, binding and distributing the "Annual Communications." In 1872, however, the entire income is entered on the credit side of the funds as "loaned to the Massachusetts Medical Society." This arrangement was continued from year to year until 1877, when, the unusual necessities of the Society apparently having ceased, the former use was renewed and the income again paid for printing and distributing the medical communications.

In 1878 a prize was offered by the Society for a prize essay, which was gained by Dr. Thomas Dwight by a very admirable piece of work on "Identification of the Human Skeleton"; and the income was devoted to the payment of the award and to the publication and distribution of this essay. During the subsequent years it has been expended as previously upon the annual medical communications, except in the years 1886, 1887 and 1888, when it was allowed to accumulate, and a prize of \$1,000 was offered for competition at large for an essay worthy of a prize, on "The Climate, and its Modifications as influencing Health and Disease, or on any of the diseases of the inhabitants of New England, or on any kindred subject." This prize failed to excite the interest and stimulate the competition which was anticipated from the offer of so considerable a sum of money, with such a wide range of subjects, and no award was made. A result which emphasized observations elsewhere made as to the diminished zeal for the capture of prizes, whether baited with a round sum of money or with a long established reputation stamped upon a medal. The time when the possession of a Boylston Prize was the almost necessary passport to subsequent professional advancement and reputation in this immediate community is in a somewhat distant past. Perhaps the appearance on the scene of the professional prize-taker has had the same limiting effect as the professional influence has had in other contests.

Be the reasons what they may, prizes seem no longer to attract as formerly.

In the years 1806 and 1807 no less than three of the Boylston Prize Medals were secured by Dr. Shattuck's pen, but in 1888 your committee came somewhat reluctantly to the conclusion that what our forefathers termed in 1807 the "beneficent and laudable view of improving the art of medicine, and the exaltation of practitioners to bring those talents to light which might otherwise be useless to the community," were not best subserved by the offer of prizes, and accordingly your council in 1888 voted:

"That the Committee on Publications be instructed to provide for a lecture, to be called the Shattuck Lecture, on some subject in accordance with what is specified in the will of the late Dr. Shattuck, the lecture to be delivered at the annual meeting of the Society."

In accordance with this vote the Committee in charge proceeded to its execution, and, apparently, impressed with the feeling that it was not intended that only the sons of the fathers should descend upon the children, they appointed me to deliver the first Shattuck Lecture before the Society.

I confess I should have been very glad for your sakes and for that of the Lectureship had the choice fallen on a more competent person, but neither my appreciation of the courtesy of your Committee nor my respect for the memory of the benefactor, after whom the Lectureship is named, would permit me to decline.

You, therefore, see why it is that you are called upon to listen to a lecture on the evening of the first day of the annual meeting, as well as to the discourse on the second day; I hope the process will not serve simply to increase your respect for the more carnal provisions of the Cotting Fund.

As the first to discharge the duties of this lectureship it may be thought proper and pardonable if I ask you to accompany me a little while in a further brief consideration of the circumstances which gave rise to its foundation, and of the scope of its functions, thus leaving a clearer field to the legitimate and more important duties of my successors.

The fund bequeathed by Dr. Shattuck to the Massachusetts Medical Society was one of three equal funds left by his will to three different societies: the other two being the Massachusetts Society for Promoting Agriculture and the Massachusetts Charitable Mechanic Association. The provisions of the bequest in behalf of this Society were that it "should apply the net interest and income of the same from time to time, in the discretion of the Society, or of its government, to the collection and publication, annually, by some suitable person or persons, of historical or other essays on the climate of said Commonwealth, or the diseases of its inhabitants, and on such other subjects as the said Society or its government may select."

The bequest to the Massachusetts Society for Promoting Agriculture — the oldest incorporated society but one in this State — provided that "the net income of its fund should be applied from time to time, in the discretion of the Society or its government, to diffuse a knowledge of the proper admixture of soils, so as to raise the greatest quantity of food with the least labor and expense; to encourage the raising of trees for fuel and ship-timber; and generally to disseminate a knowledge of practical agriculture."

The bequest to the Charitable Mechanic Association provided that "it or its government should apply the

¹ Delivered before the Massachusetts Medical Society June 10, 1890.

net interest of the fund from time to time, at discretion, to encourage improvements in architecture, and especially in the mode of constructing cheap and convenient dwellings for the poor, and also in defraying the expense of instructing mechanics' apprentices in the knowledge of the useful arts."

As has been shown by the hasty review of the uses to which this Society has put the income of its funds, the medical objects which the donor had in mind and at heart, have been, to a considerable extent, realized. The Society for Promoting Agriculture, with a total fund of about \$120,000, has done much for the farmer of the State of Massachusetts in improving the breeds of various domestic animals by the importation of foreign stock, and in other ways has disseminated a knowledge of practical agriculture; but I cannot learn that it has caused studies to be made of the proper admixture of soils, so as to raise the greatest quantity of food with the least labor and expense, or has encouraged the raising of trees for fuel and ship-timber. The generation which has grown up to man's estate since this bequest was made has solved those questions for itself in a different but a very practical way — by moving West to the plains, and to the forests of Michigan and Puget's Sound; but even there at no distant date, if things go on as they have done, if there is no rotation of crops and unchecked forest fires, such information as Dr. Shattuck thought desirable for Massachusetts in 1854 may not be superfluous.

On the other hand, singularly enough, with the increased knowledge of the diseases of domestic animals and of their relation to those of man, and with the development of veterinary science, it has come to pass that this same Agricultural Society, through Drs. Peters and Ernst, is employing a portion of its income in an investigation of tuberculosis — a disease than which there is none more prevalent, none causing so many deaths in this State and throughout New England — and is thus doing work of a kind which, thirty-five years ago, could only have been expected to emanate from medical sources.

The Charitable Mechanic Association has hitherto, I believe, done little or nothing towards realizing the specific wishes expressed by the testator, and certainly nothing especial towards encouraging improvements in the mode of constructing cheap and convenient dwellings for the poor. But other agencies have, in a certain measure, brought about this very desirable end, and capital, philanthropy and hygiene have all found a remunerative account therin.

From the last annual report of the trustees of the Peabody homes for the poor in London, in which especial attention was given to sanitary construction, it appears that the birth-rate in these homes is 8.72 per 1,000 above the average, the infant mortality is but a little over half the average, and the total death-rate is 1 per 1,000 below the average. Yet these buildings pay a moderate percentage upon the amount invested, although their construction can hardly be called cheap. Here in Boston there are now numerous tenement-houses, which fairly deserve the name of apartment-houses, occupied by poor people, where the sanitary conditions are good, the standard of health is high, there is no overcrowding, and which pay fair returns to the owners. There is also a Co-operative Building Association which aims to secure the ends sought for in this legacy, and thus indirectly lowers the death-rate of the city.

These bequests were not large — even for the day in which they were made, certainly not for ours — and were individually smaller than others proceeding from the same source, but they were eminently characteristic of the man, eminently indicative of his interests during life and of the direction which his hopes for the future took. He was not a sentimentalist, but nothing human was foreign to him; he was at home with all sorts and conditions of men, he had a constant interest in and sympathy for humanity. He knew the farmer, he knew the mechanic, he knew the homes of the poor. His father, a graduate of Harvard, a man of large frame and powerful physique, spent his strength as a country doctor in the last century, going on horse-back over the hilly regions of the northern part of Worcester County, succumbed to the exposure and labor of his profession at the early age of fifty-one years, and leaving his son an orphan at the age of eleven years. Hence, he knew, too, what it was to make one's own way; he knew — to use his own quaint expression — the value of the "healthy stimulus of prospective want," but he also knew the value of encouragement and of a helping hand held out at the right moment.

He himself graduated at Dartmouth College. As a medical student part of his time was spent at the University of Pennsylvania, where he took his degree in 1807. He obtained a knowledge of country practice by studying with Dr. Amos Bancroft in Weston, and of city practice in connection with Dr. Danforth in Boston. He had previously received a medical degree from Dartmouth, and subsequently a third medical degree from Harvard. So that, although not having studied abroad, his medical education was, for that time, a broad one.

While in Philadelphia, as his letters written from there show, he undoubtedly came under the influence, to some extent, of Dr. Benjamin Rush, who was then at the height of his reputation as a teacher, and who was a large figure in the society of the time, and he was one of comparatively few from this neighborhood who came directly in contact with Rush. Of Rush, Dr. Holmes said, addressing this Society in 1860: ²

"If I wished a student to understand the tendencies of the American medical mind, its sanguine enterprise, its self-confidence, its audacious handling of Nature, its impatience with her old-fashioned ways of taking time to get a sick man well, I would make him read the life and writings of Benjamin Rush. Dr. Rush thought and said that there were twenty times more intellect and a hundred times more knowledge in the country in 1799 than before the Revolution. His own mind was in a perpetual state of exaltation, produced by the stirring scenes in which he had taken a part, and the quickened life of the time in which he lived. It was not the state to favor sound, calm observation. He was impatient, and Nature is profoundly imperturbable. . . . Dr. Rush must have been a charming teacher, as he was an admirable man. He was observing, rather than a sound observer; eminently observing, curious even, about all manner of things. But he could not help feeling as if Nature had been a great deal shaken by the Declaration of Independence and that American art was getting to be rather too much for her — especially as illustrated in his own practice. He taught thousands of American students, he gave a direction to the medical mind of the country more than any other one man, perhaps he typifies it better

²Currents and Counter-Currents. Annual Meeting, May 20, 1860.

than any other. It has clearly tended to extravagance in remedies and trust in remedies, as in everything else, etc., etc."

Dr. Weir Mitchell, his fellow-townsman, on the other hand (*A Commemorative Address delivered at the Centennial Anniversary of the Institution of the College of Physicians of Philadelphia, 1887*), says of Rush:

"With reverent doubt of my powers to do justice to the greatest physician this country has produced, I approach the task of recalling to your memories the vivid and emphatic personality of Benjamin Rush. His life invites a less hasty biographer, and is full of such seeming contradictions as can only be explained by the belief that the earnest, decisive, and mutinous nature of a man, proud rather than conceited, got the better of the principles by which he honestly strove to guide his conduct. . . . How shall I briefly bring before you the career of this restless being? Relentless energy drove him through a life in which ardent sense of duty, large-minded philanthropy, love of country, devotion to his art and its science, immense belief in himself, were the motives to industry. . . . He was a statesman, a scholar, an army surgeon, a punctual and careful physician, an actively religious man, a far-seeing and courageous philanthropist, and a sanitarian far in advance of his day. These are what I might call four careers, in all of which he excelled, unaided by secretaries or modern means of condensing and regulating labor; one such suffices most men."

Dr. William Pepper, another Philadelphian, says of Rush:²

"Rush was evidently a perfectionist. His enthusiasm over the possibilities of human nature continually breaks out into expressions of sincere exuberance. I fear he drew his inspirations more from the experience of his own nature, refined and elevated, which required no excitement but the claims of duty, and no pleasure but the pursuit of knowledge and truth, than from the observation and study of men as they actually exist."

"The truth is that Rush was at all times and in all places and before all else a great physician. He had entered public life from a sense of patriotic duty; he had labored for the improvement of society because he was irresistibly impelled by his large humanity; but he threw himself into the service of medicine with passionate intensity. Ramsay, a favorite pupil and intimate friend, tells us that Rush wrote to him: 'Medicine is my wife, science is my mistress, books are my companions, my study is my grave.'

Dr. Shattuck shared to some extent the tendency of his day to polypharmacy; he did not eschew remedies of large bulk, he did not always think it necessary to stoop to tickle the palates of his patients, he had confidence in medicines, as he had in other methods of interfering with disease, and used them with courage when he thought interference necessary. But I do not think, in his case and in that of many others in New England, of whom he was a good type, that this was so much because he thought "there were twenty times more intellect and a hundred times more knowledge in the country in 1799 than before the Revolution"; so much because he "felt that Nature had been a good deal shaken by the Declaration of Independence, and that American art was getting to be too much for her"; in other words so much due to the

influence of the teaching of Rush — as it was due to a mental and moral inheritance typical of his time. His father, as has been said, had carried on a guerrilla warfare with disease over the hills and valleys of Worcester County for twenty-five years until he fell before it himself; his grandfather, a farmer, at the age of sixty-five shouldered his gun and followed the British on the 19th of April, 1775, from Lexington to Cambridge, having previously marched from Littleton; and his great-grandfather, also a Harvard graduate, was an Orthodox clergyman whose life was a contest with false doctrine, with the flesh and the devil. This was not a paternity for a contemplative offspring, for an expectant generation, for a hand-folding philosophy. It was in the blood to be up and doing, to wrestle with some antagonist and to strive to prevail over him; whether the antagonist took the form of a vigorous climate, of depravity of the spirit, of unjust taxation or of weakness and error on the part of the flesh. It was just possible for the strong men of that generation to sit down and see Nature lead, but not to restrain themselves from pursuing and taking hold of her when she led us it seemed to them astray. It was their duty to smite the Philistine, not to leave him the chances of the slow corrective influence of time.

The self-determining power of the will, which had accomplished much in the preceding two hundred years, had not abdicated in the early part of this century, nor yet had it adopted the gentle disguises of Christian Science, of the mind-cure or of hypnotism. Bad medicine was good for disease, as self-torture was good for the erring. We take both our religion and our medicine more comfortably and less seriously. But then he who took a distasteful remedy had placed his comfort as a precious sacrifice upon the altar of health. The nose of the patient as of every one else must be kept to the grindstone.

It was felt that the doctor's duty was to stand between the patient and the disease, but not *always* with the apothecary at his side, as appears from old letters of Dr. Shattuck's which have been preserved. A young clergyman, whose first vigor was spent, is sent on a horseback journey with a companion. Another clergyman, whose delicate wife was suffering in 1825 from some early form of tuberculosis, is advised: "If your wife can conform to rule in diet and exercise and exposure she may be restored. If the trams are too galling to her free agency she slackens the progress of cure and renders her situation still precarious. Let her case terminate as it may I feel that I have honestly intended her service. I am sorry that instinct rather than reason governs one so elevated among the national tribes." And a year later, after the death of this patient who lived at a distance: "I became quite convinced when I learned her impatience under the use of the only earthly means that could serve her (namely, warmth, rest, diet, good nursing, with the healing hand of time) that she could not attain health more."

To a college professor, who asks as to his probable future health and ability to continue in the discharge of his duties, notwithstanding an impaired constitution, Dr. Shattuck wrote in 1826: "Your diet, wearing apparel, exercise in the open air, warmth and ventilation of your apartment, bathing (medicated, warm and shower), attention to an easy state of bowels, and attention to a wholesome variety in your

² Address delivered before the American Medical Association, June, 1889.

intellectual labor and to a healthful alternation between labor and rest, are, in my opinion, adequate remedies to secure you the possession of a working power equal to all the duties of your professorship. I would underwrite at a less rate at this time on your continued life and power to labor ten years to come, then I should have felt justified in doing it at when you were here a year ago."

In another letter of advice I find the following: "You must turn Quaker, and remain silent; give your lungs rest and they will recover. After all, careful nursing is the most essential to you, pediluvium friction, diet, etc."

Yet such expectancy, such appreciation of the *circumfusa* and *ingesta*, such recognition of self-limitation proceeded from the same pen as: "Enquire of Mussey his opinion of the expediency of maintaining over your entire chest a pustular eruption for at least two or three months"; or as a prescription for thousand pills, three pills every day for a year, — a prescription the remembrance of which was treasured up unto the detriment of the third generation when applying for a hospital appointment. A compound prepared with unauthorized elegance for a rich and influential client at his request, found its way out of window instead of down the patient's throat, and the genuine stuff was procured and submitted to. It is evident that the patient was held in view for treatment quite as much as the disease. Yet, when he wished to endow a professorship at the Harvard Medical School, it was a chair of *Morbid Anatomy*, not of *Materia Medica* and *Therapeutics*, which was selected.

It is true that civil commotion stirs up thought and quickens mental activity; but, in spite of this, I am constrained to believe that the remote influence of Calvin had quite as much to do with the best of medical practice during the first half of this century in New England, as had the immediate teaching and example of Rush.

At the time the bequest which gives rise to this lectureship was made, the study and description of disease as exhibiting itself in this Commonwealth and in New England was in some ways easier and in some ways more difficult than at the present time. There was a much more homogeneous population, habituated to its surroundings and to the climate. The pursuits were less varied, the effects of competition and nervous strain less great. There was less crowding and less movement of individuals to and fro. There was less division of medical practice; there were more doctors, I think I may say — at least at the centres of population — who knew *all* about more people than now, and not merely about one member of a family or perhaps only about one organ of one member of a family. The trusted physician in the city was then, as is happily still the case in some parts of the country, the adviser, not merely the prescriber, for the family; he was in many ways the guide, the counsellor, the friend. His memory and his note books furnished something nearer the theoretical bureau of domestic anthropometry than anything we have at present.

On the other hand there were lacking the abundant facilities for rapid exchange of medical thought and observation all over the world which exists now; and there were lacking altogether or only existing in a small way, the three great sources for the study of the development, the course and the variations of disease in a given population, namely, boards of health,

hospitals and a trustworthy registration of vital statistics.

The Massachusetts Hospital was the only hospital for general diseases in New England; our State Board of Health was not started until 1869, and the registration of vital statistics, which has been enlarged and improved in recent years, was first undertaken by the State in 1842 and was much less perfect than now.

Under the circumstances, therefore, which existed in 1854 and the immediately preceding years, there was a *raison d'être* and a promise for utility in a bequest like this of Dr. Shattuck's, such as perhaps would not suggest themselves, at least not with as much force, to-day. Certainly to one who was fond of and somewhat sanguine about the compilation of facts and figures; who for many years was President of the American Statistical Association; who was a friend and supporter of Lemuel Shattuck — one of three commissioners, as Dr. Walcott reminded you last year, appointed in 1849 under the authority of this Commonwealth to make a sanitary survey of the State — to such a one the objects for which he designated this bequest, must in the early fifties have appealed with peculiar force.

Every well regulated hospital may be regarded as a post-graduate school whose courses, if rightly followed, should make some additions to the reliable records of clinical observations and to the sum total of the knowledge of disease, in its neighborhood at least. In comparison with the single hospital thirty-five years ago, one finds — in addition to the large City Hospital of Boston, the Carney Hospital at South Boston, and to all the small incorporated special hospitals doing an admirable work in this city — that Lowell has two hospitals, one organized first as a Dispensary (?) in 1840, the other incorporated in 1867; Lynn one hospital, opened for patients in 1883; New Bedford two, one opened in 1873, the other in 1885; Cambridge one, incorporated in 1871, and opened for general patients in a new building in 1886; Newton one, opened in 1886; Newburyport one, opened in 1884; Haverhill one, opened in 1882; Salem one, opened in 1874; Quincy one, opened in 1890; Taunton one, opened in 1889; Fall River one, opened in 1888; Worcester, a City Hospital, opened in 1871, and a Memorial Hospital opened in 1888; Clinton one, opened in 1889; Springfield, a City Hospital since 1879; Pittsfield, a hospital since 1884; North Adams one opened about the same time. In addition to these already opened and at work, plans are under discussion for hospitals in Malden, Marlboro' and Plymouth.

With the growth and enlargement of some of these hospitals, which the future is sure to bring, why may not fresh contributions be expected from their physicians as to the effect of locality, of certain occupations, of certain race admixtures upon health and diseases. The introduction of the Celtic element, which went on so vigorously during the middle third of this century, has had, as we all realize, an enormous influence upon the vital statistics of Massachusetts; the effect of the French Canadian and the Italian immigrations will probably be less, but just what the future alone can show. The race admixture at the Boston City Hospital is already so marked that a smattering of several foreign languages is by no means an unnecessary qualification on the part of those in attendance, and

the behavior of the Latin race under disease offers a marked contrast to that of the Anglo-Saxon.

You are all aware how much our State Board of Health has done for and through the profession in its annual publications in regard to the subjects provided for in this bequest; with increased liberality on the part of the State its work is constantly increasing; as a new progressive step you will be glad to know there is in contemplation the appointment of a salaried inspector, whose duty it shall be to investigate and report on the causes and conditions of local epidemic outbreaks, in the manner in which this has been done by such men as Ballard, Buchanan, Thorne and Radcliffe, in the service of the English Local Government Board. Here is a field of honorable medical ambition for the right men.

DISORDERS OF SLEEP: INSOMNIA.¹

BY CHAS F. FOLSON, M.D., CO-REFEREE,
Visiting Physician to the Boston City Hospital.

WHEN shall we use hypnotics? In acute disease, particularly fevers, sleep is often a necessity, reducing the activity of the heart, removing more waste, and quieting the general excitability of the nervous system. In chronic disease there is frequently the same temporary need. In incurable disorders with pain and discomfort, in the restlessness of senility, hypnotics and narcotics — and used freely in the last years of life — are almost the chief justification of our service. Often in mental disease they are, for a time, all but indispensable. In some neurotic people their occasional use can hardly be avoided. In acute nervous and mental disturbance from profound shock, full and continued uses of narcotics may dispel most threatening symptoms. The individual must, of course, be taken into consideration. Many can be depended upon to use hypnotics only as directed by their physician; others can no more be trusted with them than certain persons with alcohol. Something of slight intrinsic hypnotic value may be intensified by its mental effect, and I am sometimes deliberately asked for a prescription upon which to build a mind-cure. It is often imperative to prescribe a hypnotic, where it is best that a decided hypnotic effect should not be got. For this purpose a somewhat unpleasant drug is better than an altogether agreeable one, and the prescription which I use consists of a few minims of paraldehyde in a drachm of chloroform water. This can be repeated in the night several times and be continued without harm.

In some conditions, even with acute maniacal symptoms, it is better to let the patient lie awake almost absolutely for two or three nights than give the amount of narcotics necessary to produce sleep.

The multiplication of sleep-producing drugs has its advantages in trained, skilful hands to meet idiosyncrasies of temperament and varying conditions of disease. But the immense production and widespread use of them in the last few years must have done incalculable harm.

Very many people — highly educated as well as ignorant — firmly believe that if there is not a specific

¹ A paper read at the meeting of the Association of American Physicians, Washington, May, 1880. Concluded from page 6 of the Journal.

for their malady the reason is that it has not been brought to light; and they not only demand repeated trials of useless remedies but assiduously follow enticing promises in regard to those that are even injurious. When our advice does not meet their fancies in that regard they continue their search for what they crave.

The greater one's experience, the more is he satisfied how little he can do as compared with what the community insists upon expecting, although more and more convinced of the great value of that which can be done, of the harm of overdoing, of the need of minute study in each case, and of the vagueness of general rules of treatment. The chief indications in insomnia are: To give hypnotic drugs rarely and only in cases when other measures have failed; to use, as far as it is possible, the small dose, repeating as needed, so as to avoid the over-action or the cumulative effect of large doses; to be satisfied with the least amount of sleep that is safe if produced by medicine; to avoid drugs as a rule, except for euthanasia, when the mental condition is not such that all the after-effects can be noted; to bear in mind the fact that hypnotics given to produce sleep may increase wakefulness; to be on guard for unpleasant or toxic results when any drug is given in sufficient dose to produce prolonged and profound sleep; to give the large dose when it is indicated; to not expect the same action or tolerance of new medicines in sensitive private patients as in hospital practice.

Of hypnotics, there are probably none that can be continuously used for a long time in sufficient doses to control troublesome insomnia without occasional dangerous symptoms or unpleasant after-effects, although I have no doubt that many of the accidents reported as due to them are rather coincident with them than consequent upon them. Most cases, however, are not intractable to treatment, and many respond readily to domestic remedies, like skullcap, thoroughwort, sage-tea, glycerine, or hot punch, without the physician being called, or perhaps their restlessness has been controlled by hyoscyamus, valerian, cannabis Indica, camphor.

The advantages of spirits, wine, beer, ale, porter (including some of the so-called malt extracts), koumyss, matzoon, are well known in old age, conditions of exhaustion, fevers, and generally where a cardiac depressant must be avoided; especially if supplemented by vaso-motor stimulants, like ergot, digitalis, strychnia, coca, cocaine. A glass of champagne often acts like magic in the sleeplessness of a dilated heart. A few bottles of beer at bedtime may control persistent and obstinate sleeplessness which has yielded to nothing else. But the habitual necessity of alcohol to produce sleep in brain-workers indicates the nearness of the danger line. The disadvantages of alcohol are well-known and readily guarded against.

The preparations of opium are indispensable in many cases — with pain, in old age, in many forms of heart disease. I have not found the common caution against opium in pulmonary and renal disease valid, and probably no other drug can be made to so happily meet the indications of so many conditions, except for the grave danger of the morphine habit. Kraft-Ebing names it justly a tonic to the asthenic brain. In euthanasia, its value is shared with only ether and chloroform.

The bromides diminish the reflex excitability of the medulla, and are vaso-motor excitants. Their best

therapeutic effect, always avoiding bromidism, is got, as hypnotics, from divided doses given through the day or evening, whether in large quantity or small. Alone or combined with other medicines they have a wide usefulness. The debilitating influence from them may in some cases be, partly at least, met with iron or bark. By virtue of obstructing the heart's action, and producing a certain degree of muscular depression, they are not without objections for continued use, or, in some cases, occasionally.

The great need of an unobjectionable hypnotic led to constant laboratory research, and the final discovery by Liebreich of *chloral-hydrate*,⁴ Eickhoff's *schlafmittel* *karb. lösyr.*, the most powerful of pure hypnotics, having also some influence on pain. In sufficient dose it rarely fails. Alone or combined with bromides or morphia, it used to be, until the introduction of paraldehyde, the common last resort when other narcotics had failed. Its depressing effect on the heart, respiration and vaso-motor centres, which, perhaps, includes its toxic or irritant action on the kidneys, and the danger of the chloral habit, with persistent wakefulness and mental enfeeblement, constitute the risks in its use.

Croton chloral, the butyl-chloral-hydrate, or, chemically, the chlorated aldehyde of crotonic acid, although not a cardiac depressant, is, in all other ways, so inferior to chloral-hydrate, besides being not readily soluble in water, that it is rarely used except with trigeminal neuralgia, in which it is less efficacious than other drugs.

A less depressing hypnotic being sought for, the fat series came next, paraldehyde, amyl-hydrate, urethan, hypnone.

Paraldehyde,⁵ a polymeride of ethylic aldehyde—long thought second only to chloral-hydrate in power as a hypnotic—has much less depressing action on the circulation and respiration. It is especially valuable in conditions of mental excitement, where the duration of sleep may be prolonged by adding morphia. The physiological action is first on the cord, and then on the medulla. Toxic doses (ten grammes or more) produce a sinking of blood-pressure and slowing of the heart beat; doses of six to eight grammes having been observed to give rise to nausea, headache, confusion, vertigo, and weak pulse. In five cases Berger found material reduction in the quantity of urine. In safe doses it is not anesthetic or analgesic. To get a definite hypnotic effect, the dose must be increased. Its acid taste, and the disagreeable persistent odor from the breath are objections to its use, and even when largely diluted it is often objected to, on the ground of its being a gastro-intestinal irritant.

The temptation to its habitual use is less than in alcohol, morphia, cocaine, and chloral; the symptoms produced being tremor, confusion, impaired memory, diminished intelligence, etc.

Dose, two to four grammes, which, if necessary, may be gradually increased to eight, and repeated once or twice in the night.

Amyl-hydrate,⁶ a tertiary amylic alcohol, an oily,

⁴ An abstract of recent articles on the new hypnotics was intended as an appendix to this paper, but the amount of material (over one hundred foolscap pgs) was too large to justify its space, and its appropriateness here whether in full or condensed has seemed to me at least doubtful.

⁵ Albertoni, Berger, Butler, Cervello, Cervello and Valenti, Clouston, Fawcett, Gellhorn, Henocque, Hodgson, Kenniston, Kraft-Ebing, Liebreich, Peretti, Quinquared, Rank, Rothe, Strahan, Tepehew, v. Noorden.

⁶ Buschan, Dietz, Egasse, Eshoff, Jolly, Griffith, Gürthner, Lehmann, Liebreich, Mason, Mayer, Riegel, Savas, Scharschmidt, von Mering, von Mering and Thierfelder, Willis, Wurtz.

colorless liquid, appears to stand in hypnotic power below chloral-hydrate, and above or below paraldehyde, according to different observers, but with even less depressing action on the heart than the latter. It may be used in about the same dose as paraldehyde, being not so soluble (1 to 19 water, freely in alcohol), and with a much less disagreeable taste and odor. Its physiological action is directly on the cerebrum, and later on the medulla. The toxic effects from it, of headache, nausea, weak pulse, are less marked than in paraldehyde, and it is less a gastro-intestinal irritant, although sufficiently so to often require its administration by rectum.

Urethan⁷ (ethylic carbamate) a mild hypnotic in doses of twenty grains, is at times useful, and may from its ready solubility be given hypodermically. It is without especial depressing action on the heart, except in enfeebled persons. It has, like all rather mild remedies, proved in some cases uncertain in its effects, but is useful and ordinarily without disagreeable after-effects.

Hyoscyamine⁸ isomeric with atropine, in doses of $\frac{1}{2}$ mgm. of the sulphate, which may be given subcutaneously, controls moderate mental excitement and sleeplessness. In larger doses similar toxic effects to those of atropine are observed, sometimes with muscular prostration, which may reach an alarming degree. Of some value in hysteria with violence, its use is very limited.

Hyoscine,⁹ also an alkaloid of hyoscyamus, is used as iodohydrate, chlorhydrate, and, preferably, hydrobromate, also hypodermically, in doses of $\frac{1}{2}$ to $\frac{1}{4}$ even 1 mgm. It has a limited usefulness, especially in maniacal excitement, violent hysteria, delirium tremens, insomnia with agitation, in the insane and aged. The dose needs to be increased somewhat rapidly for prolonged use, and a slight excess in the quantity given may produce unpleasant toxic effects, which may even come from $\frac{1}{2}$ mgm. In a certain proportion of cases not only is there no quieting effect from the drug, but the restlessness is increased.

Chloralamide,¹⁰ or more properly chloral-formamide, produced by adding anhydrous chloral to formamide, is decomposed again in aqueous solution (1 to 9) if above a temperature of 60° C., or in crystals if above 115° C. It is also decomposed by alkalies and alkaline carbonates. It is, therefore, well to give it in slightly acid solution, with spirit, or as an elixir, thereby sufficiently disguising its bitter taste. It is claimed that it possesses all the advantages of chloral-hydrate, and on account of the stimulating properties of the formamide, without its depressing action on the heart, a fact verified by the sphygmograph, the comparative dose being as 3 to 2. The danger from the larger dose, over 30 or 40 grains, is less than in chloral. Disagreeable after-effects are much less common. Some observers value chloralamide most highly, while others regard it as in no way deserving especial praise. In my experience, with only the small dose, it has done well. If it shall be proved, after full trial, to be safer

than chloral, and more certain than the other pure hypnotics, as it is claimed to be, its cheapness is in its favor for general use.

Sulfonal,¹¹ diethylsulphondimethylmethan, is a less powerful hypnotic than chloral, with even less influence on pain, but without so much, although with slight, depressing action on the heart. From its difficult solubility, the physiological action is slowly produced; a single dose may be efficient for two successive nights, and there is risk of the cumulative effect if the dose is too often repeated. It may be given in compressed tablets or wafers, or dissolved in spirit. In doses of 30 grains or less it is, in the main, safe, although I have seen 20 grains given each night for several weeks in a girl of sixteen produce stupor, and 20 grains, three times a day continuously, to a strong male adult, cause ataxia, tremor, and mental apathy. It has been found not always certain, and, in overaction, with an after-effect of somnolence, fatigue, depression, lack of appetite, which, from an over-dose, may amount to semi-coma and cardiac depression. Given in doses of 5 grains, and repeated, if necessary, two or three times, or of 10 or 20 grains, and perhaps repeated, it has proved in my hands, a hypnotic of great value in producing sleep which is refreshing and resembling the natural. When care has been taken not to give it too often or in too large doses, I have never seen any untoward results from it. In the case of a rather delicate person, 150 grains produced sleep with stupor for ninety-six hours, but no other unpleasant symptoms, except some lassitude and a sense of discomfort in the head. It is the most important and widely useful of the new hypnotics.

Hynpone¹² (acetophenone, phenyl-methyl acetone), one of the aromatic series of acetones, although praised by Dujardin-Beaumetz, has proved in the hands of most investigators of little value as a hypnotic, of unpleasant taste, and depressing to the respiratory and cardiac centres.

Ural¹³ (chloral-urethan) is less potent than chloral, and more so than urethan. It is very bitter, soluble in alcohol, and but little so in water. In doses of more than two grammes there may be transient headache and fatigue.

Somnal¹⁴ (ethyl-chloral-urethan) contains four atoms of hydrogen and two of carbon more than chloral-urethan (ural). It appears to have no especial advantage over chloralamide, except that it is more soluble. It has somewhat greater hypnotic power than ural. Its composition is not regarded as certain or its action sure.

Acetal¹⁵ (diethylacetal) is an acrid hypnotic without advantages to compensate for its being a gastrointestinal irritant.

Methylal,¹⁶ an acetal derived from formaldehyde and methylalcohol, a volatile liquid freely soluble in water, of fragrant and aromatic odor, almost tasteless, may be inhaled or given by mouth and hypodermically. It has the high authority of Kraft-Ebing as being a safe, certain hypnotic, useful in some forms of

insanity with excitement, and especially in delirium tremens, for which he considers it the best hypnotic known. He uses 0.1 grammie with 1 grammie water, hypodermically, repeating every two hours if necessary. The dose internally is m_l . 30 to 3ij. The depressing effect on the circulation is slight, if any, and he has not observed any disagreeable after-effects. It is contra-indicated in conditions of active cerebral hyperemia. Kraft-Ebing is in doubt how to explain the efficacy of the extremely small dose used by him unless it acts indirectly rather than as a direct hypnotic in producing sleep. Lemoine gives two grammes subcutaneously.

Phenacetin,¹⁷ para acet-phenetidin, almost insoluble in water, soluble in alcohol, almost tasteless, may be given like sulfonal, in wafers and compressed tablets, as a powder or with brandy. As an antipyretic and antineuritic it is not as potent as antipyritin and antifebrin, but it is much less a cardiac depressant. In the insomnia of overwork, of nervous irritation, in febrile states, or from headache, it is a hypnotic of great value, in doses of five or ten grains, repeated if necessary. In sleeplessness of intense neuralgia, less than a grammie repeated two or three times, as needed, is not likely to be effectual, the fact having been first ascertained that there is no intolerance of the drug.

The possible analin derivatives of, which phenacetin (para-aethoxy-acetanilid), acetanilid and methacetin (paramethoxy-acetanilid) have thus far alone been used in medicine, together with numerous known compounds of not ascertained value, indicate the boundless possibilities for the future in this direction.

Acetal, ural, hynpone and somnal do not seem to me to have sufficient therapeutic value to justify their existence. Hyoscine and hyoscyamine have a limited range. Of the other hypnotics we must trust somewhat to experience in ascertaining which is least likely to disagree with a given patient; and to one already discouraged by long illness an unsuccessful trial of a new remedy may be so unsuccessful as to be disastrous. Personally, I use them sparingly, and as indicated. There are cases where very large doses of powerful hypnotics must be used to produce sleep or else alcohol freely. On the other hand, most patients sleep better than they think and many sleep enough who believe that they sleep scarcely at all.

A GYNECOLOGICAL CASE.¹

BY W. S. EVERETT, M.D., HYDE PARK.

On the second day of May, 1888, a young, very attractive and intelligent lady, hitherto a stranger, called at my office for advice and direction, if not treatment. Her look was anaemic; her expression was troubled; her countenance was pale, colorless, like that of one who has been blanched from loss of blood. Her bowels were constipated, her appetite was poor.

This is the history that she gave: Her general health had been fairly good in her childhood, and until the menses appeared. Since that time, a strain of excitability or of depression had been worked into her history, that, accompanied by the disturbance of the menstrual molimen, had been the occasion of a

good deal of trouble, and had kept her quite frequently in the physician's care.

She was twenty-three years of age. She had been in the care of one of our Norfolk County physicians in her earlier days, and he, it seems, not being quite satisfied with the results of treatment on general principles, had advised her to consult some specialist.

Her troubles at this time were, according to her statement, a general prostration, which did not improve under tonic treatment, severe pains in the back, which, some two and a half or three years previous to the time of our interview, became transferred to the right hypogastric region where they had since remained, and had recurred at irregular intervals of from one to two weeks, from that time on, increasing in severity, until the anguish occasioned by them had become intolerable and had compelled her to seek relief.

The catamenial flow came on when she was fourteen years of age, but had never been in any degree regular, varying in times of its occurrence from six weeks to eight months. I do not find anything in my notes that enables me to say positively whether the intense suffering was relieved temporarily after the flow appeared, and I very much regret the omission.

As a result of the advice of her former physician, she consulted a noted female physician of the city, who gave her "local treatment" as she said, which meant that she applied tincture of iodine to the mouth of the uterus, though she told her from the first that she did not find anything in particular to be wrong with her in that region. But these frequently recurring attacks of pain were not relieved, and she afterward consulted another prominent practitioner of the city, who, after examination, referred all her troubles to disease of the ovaries, and advised their extirpation. For this measure she was not prepared, unless farther advised and different or, at least, corroborative counsel decided it to be imperative, and she consulted another leading physician of his time, who has since died. He advised strongly against the removal of the ovaries as matters then stood, and not making a positive diagnosis of his own, referred her to an eminent specialist of the city, to whose office she had made some six or eight visits previous to calling at mine.

He had made as thorough examinations as the case would admit at these interviews, and his investigations had been as exhaustive as he could make them, and he wrote to the physician, by whose advice she had consulted him, stating that he found the lower portion of the right kidney tender and manifestly diseased; and accounted for the pain, that had come to be terrific in its violence whenever it recurred, by regarding it as a renal colic, for which, he said, the removal of the ovaries could be expected to do no good.

She was married on the eleventh day of November, 1886, two days after the cessation of a menstrual period. The interval between that period and the last preceding period had been nearly four months, and its latest predecessor had been in the preceding February. It was, therefore, manifestly impossible for her to fix her wedding-day with any reference to that time, and it happened, as stated, just before her marriage, and terminated only two days before that event. Possibly the exhilarating excitement of preparation for that occasion may have been one of the predisposing causes that brought it on at that time. But it came, at all events, then, though she was not in the least troubled

by the fear of what might happen, and did not look upon it as in any way an unfortunate circumstance that it should happen just as it did.

Her next appearance occurred in October, 1887. Meanwhile she had supposed herself to be pregnant, but she did not expect to be eleven months about it, and she had not gone along otherwise just as she thought she ought to, if such were the case, and she consulted another physician, whose name, for some reason, she declined to disclose, who told her she was about three months along. When this period came on, in October, 1887, she flowed excessively, and suffered much. In fact, her periods, whenever she did have them, were excessively painful and very profuse, being bright red blood at commencement, becoming more profuse as days went on and finally ending with clots of considerable size and quantity, and in this particular instance, disappointing all her hopes and materially jeopardizing her prospects, whatever they might be, of ultimately rearing a family, and she was much inclined to yield to discouragement.

After this period in 1887 had terminated, she again hoped that she might be likely to become a mother; but, of course, she could not have become pregnant then, she thought, because the indications must have been unmistakable by the present time (May 2d) if she had done so.

In February, 1888, the breasts became hardened and tender, and had remained so, growing constantly larger. The nipples, at this time of her visit (May 2d), had also become more prominent than they had ever been, the areola had become puffy in appearance and darker in color, and the follicles were very considerably enlarged. There was no examination, except of the breasts, at this interview, though the abdomen was felt through the clothing to be tense, firm and apparently much larger than in its ordinary condition.

Such, now, is a description of my patient, and her present condition stated with as much accuracy as it is possible for me to give it.

Here she sits in my office, on this May afternoon, and tells of all the suffering that she has experienced, tells also of all these various, yes, celebrated ones whom she has consulted within the last three years, of whom the first is committed to no statement of opinion, so far as is known, concerning the nature of her troubles; the second, with large experience and extensive practice, had failed to find any indication of disease of any kind; a third, eminent in his profession, had diagnosed disease of the ovaries, and advised their removal; a fourth, had declined to make a diagnosis; a fifth, still more eminent in his specialty, had found the right kidney diseased; and yet a sixth had pronounced for pregnancy at three months; she tells also of the yet unabated and frequently recurring paroxysms of intolerable suffering, tells of the unexplained and extreme irregularity of the menses, and of her marriage. By personal observation also, she is found in the general unsatisfactory condition that has been described, with prominent abdomen, large and dark colored nipples, puffy areola, with follicles enlarged, and with the history, as given, extending over all this period of years.

It would have been a great comfort to me at this stage of our interview, if I could have excused myself for a moment from the presence of my patient, and, finding our club in convenient session within accessible distance, have hurriedly laid my case before it

and asked what answer I should make to the woman when she asked me the question which she did ask me, "What is the matter with me?"

But there was nothing of the kind to come to my assistance, and I was obliged to rely on such resources as I had. And I saw nothing better to be done than to tell her that I could not expect to form an opinion concerning the cause of the suffering that she endured at a single interview when so varied opinions had been given by so many competent practitioners in the matter, and that as to the question of pregnancy, if a woman were herself in doubt in the early stages as to her condition, I could not, and did not have much confidence in the opinion of any who thought they could tell with any degree of certainty whether she were pregnant or not.

But in view of the increasing size of the abdomen and the behavior of the breasts, I felt warranted in expressing the opinion that the probabilities pointed in the direction of her being in a family way. And here the interview ended.

The next morning, May 3d, with very little regard evidently for the sanctity of the doctor's opinion, she sent me a note, stating that she had "come round" as she expressed it, emphasizing the words with a line drawn under them, and would like to have me visit her that day, which I did. She had been in doubt how to proceed. Whether it was best to try to promote a more copious flow; or to try to stop it altogether, she did not know.

She had feared that being in a family way, it might be a threatened miscarriage, and that the means that should promote it, might induce just what she was anxious to avoid. Yet if it was only an erratic or comet-like return of what should be depended upon to come with regularity until there was good cause why it should stop, then there seemed to be no reason why it should not be encouraged in every way. I told her to promote it by every means, and gave such direction as seemed to be calculated to bring about that result. She went through that period regularly enough, and it turned out to be a regular period and nothing more, and the case stood precisely as it had stood for years.

It is interesting in the progress of this case, to note the recurrence of the catamenial flow, and I am able to give the times of its appearance with accuracy for the preceding four years. It came in March or April and in October, in 1884; that was when she was nineteen years of age, and five years after commencing. It came in January and September, November and December, 1885; in February, July and November 6, 1886, and she was married on the eleventh. The next and last appearance, previous to her visit at my office was October 11, 1887, just eleven months precisely, from the day of her marriage. Ten times then it had appeared, when it should have come fifty. What could explain it? what could be the cause? I decided upon two things. First, that none of the old trials that had been worked thus far were ever going to lead up to an explanation of this condition in a young woman apparently otherwise in good health, and possessed of all the attributes that belong to a woman of her years. Second, that if mechanical obstruction to the flow of the menses were present, it might furnish a more consistent explanation of all her experiences for all these years, than any theory that had yet been applied. One thing seemed pretty clear. The desire of her heart like all who begin to

fear that the privilege of rearing a family is to be denied them, was set upon having children. It did not seem probable now as things looked, that it was likely to be gratified. She had been married now nearly two years, was married at a time when she thought immediate pregnancy was to be expected, had raised her hopes to the highest pitch of expectancy when the enlarging abdomen seemed to give evidence that her desires were likely to be fulfilled, and then after eleven months of uncertainty and anxious expectation they had been dashed out unceremoniously by the unwelcome return of October, 1887, to be again raised by the changes that had taken place in the breasts and nipples and areola, and the still increasing size of the abdomen, only to be stranded in hopeless despondency and disappointment by this last appearance on the 3d of May.

I determined to act upon the supposition that the menses were retained. It seemed reasonable to suppose that if the secretion took place regularly within the uterus and for any reason was not discharged, that the time would be likely to come when its presence would cause pains that might be in the nature of uterine contractions, and that would increase in severity until they might answer the description given in this case, and that they might continue until they had so far overcome the obstruction to their free exit, whatever it might be, as to force out a portion of the confined mass sufficient to afford relief, until the accumulation had again become so great as to excite a recurrence of the pain, to be again relieved, only by the same means. And here it is that my notes would be so much more valuable, if I could say positively that the suffering was relieved for the time after the flow came on. But I have not the knowledge in my possession that justifies me in making that statement, though I believe it to be true.

If this theory were correct I thought also it might explain why pregnancy did not occur. I determined to find an entrance into the uterus and to force one if necessary, though of course there was an opening, otherwise the menses could not by any possibility have been discharged, and Byford says that in many cases where the os externum was not larger than a small pin-hole patients have menstruated regularly without any pain whatever. Whether pregnancy is obstructed by such condition, he does not state.

How should the operation be performed? It did not seem to me that the sound was the best instrument for it as it would leave an opening smaller than it was desirable there should be, and I feared to use either the knife, the scissors or dilators, fearing that I might set up an inflammatory action in the uterus of a woman of her nervous sanguine temperament, of which the end could not be foreseen. I finally decided to make use of a large silver probe with a very large bulbous extremity designed, I think, for probing gunshot wounds of considerable depth, which would make a larger opening than the sound, without incurring the dangers of the tent, the scissors or the knife.

I waited until the time came for the return of the period in June, and it did not appear, and it seemed useless to delay longer. The probe was forced through the external os, meeting with a good deal of resistance, but it was pushed onward as far as I dared to force it, meeting an increasing degree of resistance all the way. Finally I desisted, more because I did not dare to exercise the force necessary to carry it

farther, than because the purpose of the operation had been accomplished, for of this I did not feel at all sure.

But I told her we would wait another month and see what happened. If necessary the operation could be repeated, perhaps more effectually. If it should not be necessary, we would all feel relieved.

One point, at least was gained. I felt sure that whatever else might happen, we had no pregnancy to complicate the case. And I represented to her the advantage of abstaining absolutely from all the possibilities, whereby pregnancy could occur, until her status could be still more definitely determined; telling her that for our present purpose, the next best thing to knowing that she was in a family way was to know that she was not.

There is every reason for believing that my injunction was implicitly obeyed. She had begun to take courage in the prospect of a new departure, and was ready to aid my measures in whatever depended upon herself.

But when the month came around, and I came to make my promised visit, I found the shutters up and the house closed. The family had disappeared. I supposed she had become disgusted either with the doctor or with his treatment, and had gone elsewhere to add another to the list of unsuccessful ones, into whose hands the fates had directed her steps and I expected to see her no more. But one day, late in October, she reappeared to me and explained her absence and told of all that had happened since she had been away. It had seemed best, in order to carry out my wishes, that she and her husband should dwell apart for a time, and so, previous to my call in the early summer she had taken up her residence at the seashore, and the husband had provided himself with quarters elsewhere. Her June period she missed, but in July she came on regularly and on time and got through it more satisfactorily than for years. In August, to her great delight, she came on again regularly, and on the twenty-fifth of that month marital relations were resumed.

Our case loses its interest from this time. No renal colic has since been reported; the kidneys, both right and left, appear to be performing their function satisfactorily, and unless the ovaries shall yet develop some still more urgent symptoms, their expiration will probably be indefinitely postponed, and the full measure of parental happiness reaches its climax in the circumstance that on the 12th day of June last, two hundred and ninety-two days after the family had been re-established, there came into the household a fine healthy boy that is the pride and the delight of all who take interest therein.

Reports of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.¹

DR. CHARLES H. KNIGHT of New York, reported a CASE OF FIBRO-SARCOMA OF THE RIGHT NASAL FOSSA, WITH UNUSUAL CLINICAL HISTORY,

accompanied by a specimen.

The growth in this case had its origin in the nasal cavity. Baker, forty-two years. Family and private health good. Twelve years previously he received a

¹ Report of the Twelfth Annual Congress, at Baltimore, Md. Concluded from page 14 of the Journal.

blow upon the bridge of the nose, to which he attributed his malady. For two years had had nasal obstruction, gradually increasing; frequent sneezing; constant frontal headache. Disposition became irritable, and used liquor to excess contrary to previous habit. No hemorrhage, until two months ago, when he expelled from the right anterior naris masses of bloody tissue, and about the same time expelled a fleshy mass as large as a robin's egg from the posterior nares. The right eye became closed by edematous swelling of lids and infra-orbital region. The right nasal chamber was found completely filled with a soft vascular and very sensitive mass resembling an old myoma. Part of the growth was snared off, and profuse hemorrhage resulted. The growth was rapidly reproduced in the next few days.

The patient then went to the hospital, where Dr. Weir performed Chassaignac's operation. Part of the growth was everted off, when it was found that it involved the ethmoidal and sphenoidal cells, and the operation was carried no further. The patient made a good recovery from the operation; but the growth redeveloped in six weeks, and involved the face. Three months after the operation, the patient in a delirious condition, tore out a portion of the tumor by putting his fingers into his mouth and dragging out an irregular mass, which was from the naso-pharynx. The rush of blood was very great, but ceased spontaneously before the arrival of the physician. The patient was exhausted, and died five hours later. No autopsy.

The paper was largely devoted to a consideration of the literature of the subject, and the methods of operation. The lecturer favored a radical operation such as Maissonneuve's, when the growth shows any tendency to malignancy. The theory of traumatism was declared insufficient to cause the morbid action. It alone is not capable of creating malignancy. Microscopic examination of the specimen showed the characters of fibro-myoma.

DR. BOSWORTH deprecated severe measures. The only case of recovery from sarcoma that he knew of was one in which severe measures could not be borne. It was reported at the meeting of the American Medical Association several years ago. Butlin says that it is at first a purely local disease. The old operations are unnecessary. At the present day all parts of the nose are accessible without such severe operations, and the growth can be snared off. In carcinoma no treatment is of service.

DR. MULHALL reported a case of small-celled sarcoma, filling both nostrils. The case also had some interest in connection with the question of the origin of the disease from injury. The man was injured on the railroad about a year before the disease appeared. When first seen, a mass of soft material projected from both nostrils; it bled easily. The galvano-cautery was used to clear one nostril after several sittings; but he became tired of treatment, took to the use of morphine, and died in four months. The disease lasted about a year.

DR. BOSWORTH: The case is reported as one of fibro-sarcoma. It would be interesting to know whether it changed in appearance at the time it took on malignant growth.

DR. KNIGHT said, with regard to radical measures, he would not advocate any except the operation of Maissonneuve.

ADENOID TISSUE IN THE NASO-PHARYNX AND THE PHARYNX. A PRELIMINARY REPORT ON THE DEVELOPMENT AND EARLY HISTORY.

was the title of a communication read by DR. H. L. SWAIN, of New Haven, Conn.

The paper considered the adenoid tissue in this locality as a whole; that is, the ring of tissue formed by the pharynx tonsil above; next the tissue in the region of the tubes on either side, then the lateral column of the pharynx, the faecal tonsils, and, last of all, the lingual tonsil. This ring of tissue is right at the junction of the tissues formed by the exoderm and the endoderm of the embryo, and is itself formed by the participation of the endoderm as motive principle and the mesoderm as origin of the cell infiltration.

In studying the development, it was found that the pharynx tonsil was the earliest to begin, as it is the oldest gland in the comparative history, being found in the lowest form of animals. Next in age were found the faecal tonsils; while the youngest member of the group, or at least the latest to form, was the lingual tonsil. Thus there is a physiological basis to observed phenomena of early atrophy of pharynx and late endurance of the lingual tonsil. The beginning of all these different portions of the ring of adenoid tissue in the embryo was alike, not varying as does the tissue. The bursa pharygea of Luschka seems to have a somewhat inconstant embryonic existence and must not be confounded with the recessus pharyngeus medius, which is a more frequent occurrence in the well-developed organ.

The constant appearance of follicles in all parts of this tissue is a normal phenomenon, but is, unquestionably, as observed in the lingual tonsil, influenced by pathological changes. That is, disease favors an earlier appearance of the follicles and makes an increase in their size and number. The conglobate glands in the pharynx tonsil possess no hollow spot.

In considering the function of the adenoid tissue, many views were spoken of, but credence given to a two-fold purpose which this tissue fulfills, namely, an organ for the formation of leucocytes, which amoeboid cells, by virtue of their immigration to the surface, come into a position to meet micro-organisms and protect the system from their influence by destroying them. Secondly, there seems to be a direct relation between the number of leucocytes present in this adenoid tissue and the demand of the rest of the system for those cells; for, in cases of long-continued purulent process, there is a great diminution in their number. From the first we may deduce reasons for the larger development of adenoid tissue in man and in certain animals; from the second, an explanation of the atrophy of this tissue in many observed cases.

DR. BOSWORTH complimented the author upon his paper, as the function and pathology of the lymphatic structures of the nose and throat are now occupying considerable attention. The suggestion by Scanes Spicer, that the tonsils are placed in the throat to absorb excess of fluid, does not amount to the dignity of a physiological theory. Killian's view was that this adenoid tissue is placed here to destroy micro-organisms, but they might just as well be looked upon as traps for micro-organisms where they develop. A very interesting question in catarrh is, Where does all the fluid come from?

Remarks were also made by DR. LANGMAID and the author of the paper.

DR. E. FLETCHER INGALS, of Chicago, read a

SUPPLEMENTAL REPORT ON CARTILAGINOUS TUMORS OF THE LARYNX AND WARTY GROWTHS IN THE NOSE.

The first case had been reported to this Association two years ago, when still under treatment by applications of chromic acid full strength for cartilaginous growths just beneath the vocal cords. Although a practical cure seemed to have been obtained, the patient afterwards returned with slight thickening of the base of the growth, which required several subsequent applications. During the past year, there has been no recurrence. At present the mucous membrane appears healthy; no cicatrix. The acid seems to have caused absorption rather than destruction. At the last meeting, a case of similar growth in the nose was reported, which resisted chromic acid, nitric acid, galvo-cautery and other means. Subsequent applications of tincture of thuja occidentalis upon a pledget of cotton (twice daily) with internal administration of drachm doses three times each day, was followed by improvement. Occasional applications of chromic acid were also made about once a week. This was followed by complete disappearance of the warty growths.

DR. BOSWORTH referred to a case seen some months ago in a child three months of age. It was a broad, papillary growth on the tongue and palate. He applied thuja, but without result. The growth was afterwards completely destroyed with acetic acid. They are like warts on the skin anywhere.

DR. MCLHALL considered that some confusion existed between soft growths and papillomata. A paper published some time since stated that the writer had seen several hundred cases of warty growth. The diagnosis can only be made with the microscope. He had individually seen only a single case of papilloma of the nose. It sprang from the anterior end of the middle turbinated bone, and looked exactly like a bunch of grapes.

DR. JARVIS advocated the use of chromic acid in removing papillomatous tissue, as the best caustic. He agreed with the last speaker that papilloma of the nose is rare; he had seen only two cases.

DR. MACCORY had treated three cases of warty growths from the vestibule with the galvo-cautery.

DR. MULHALL said that he would have a microscopic examination made, and add it to the report of the case.

DR. S. O. VANDER POEL, of New York, reported a

CASE OF MYXOMA OF THE EPIGLOTTIS,

and presented drawings of laryngoscopic appearances.

The patient, a German, fifty-four years of age, a blacksmith, was well until seven months previous to coming under observation. He then had difficulty in deglutition and the sensation of a foreign body in the throat. No actual pain. Talking required effort, only occasional hoarseness, with feeble whispering voice. Suffocative attacks at night, waking suddenly from his sleep, owing to some mechanical obstruction. He lost flesh rapidly, owing, he thought, to the small amount of nourishment he had been able to take. Cough had been troublesome, and especial difficulty was experienced in removing mucus from the throat. Mitral

cardiac murmur, bronchitis and emphysema were present. There was slight hypertrophic rhinitis, with eochondroma of septum. With the laryngeal mirror, a growth of yellowish-red color, translucent, about as large as a horse-chestnut, was seen springing from the lingual side of the epiglottis; surface glistening, lobulated and traversed by numerous small vessels. It was attached to gloss-epiglottic fissure of left side. It was so large as to prevent examination of larynx, only a small portion of vocal cords could be seen. The growth was removed with the galvanic écraseur. The patient did not show much improvement after operation, but progressively failed, and died some four months later with all the appearances of leucocytæmia. No malignant disease was discovered post mortem. The growth was a myxoma, and was attributed to the general disease, such growths being characteristic of leucocytæmia.

A review of the literature of the subject was appended.

The PRESIDENT remarked that, whereas the growth in the location described by the lecturer is rare, the same growths lower down in the pharynx are not very rare. He had seen a large number at Hyrtl's Clinic in München.

DR. LANGMAID said that it was a new thought to him that these growths might be myxoma.

DR. SWAIN had removed from the fossa glosso-epiglottideus a growth just at the junction of the epiglottis and tongue, which proved to be a simple polypus; strictly a mucus polyp resembling those from the nose in every particular, except that it was more consistent. It did not contain lymphoid tissue.

DR. VANDER POEL said that his remarks applied to a pure gelatinous growth characterized by stellate cells, with delicate processes interlacing, imbedded in a gelatinous ground substance. He regarded Dr. Swain's case as analogous.

The PRESIDENT remarked that such growths are most frequently fibro-sarcomatous in character.

HOARSENESS AND LOSS OF VOICE CAUSED BY WRONG VOCAL METHOD,

was the title of a paper by DR. S. W. LANGMAID, of Boston.

The evils of unnatural and unphysiological methods of voice-training pursued by some singing-masters was the chief topic considered, and especially, the forcible holding of the tongue down, during the formation of different tones. The idea that this gives increased room in the larynx and air-chambers is erroneous, on the contrary it interferes with the proper physiological action of the muscles which control the movements of the larynx and calls upon them to do two different duties at one time. One singer can get the best effects with the tongue flat, another will get her best results with the tongue partly raised. There is a great difference in the size and shape in different tongues; the aim is to obtain the tone in the most natural manner in the individual. Cases were cited to show the effects of overstrain, temporary paresis, hemorrhage, etc. Treatment is rest and adoption of a natural method.

This paper was discussed by DRs. DELAVAN, HINKEL, MULHALL, MACKENZIE and LANGMAID; and the conclusions as to the effects of wrong method and strain of voice concurred in generally and the treatment by rest and proper vocal gymnastics approved.

The afternoon session on the second day was opened by a paper on

THE CONDITION KNOWN AS CHORDITIS TUBEROSA, read by DR. CLARENCE E. RICE, of New York.

The following conclusions were formulated:

(1) That the condition known as chorditis tuberosa is *not* one of the pathological changes to be classed among those of chronic catarrhal laryngitis, but it is itself the primary lesion.

(2) The presence of this nodule is the direct cause of the catarrhal changes in the larynx, which are developed later.

(3) This condition is almost always found in singers and public speakers, and is caused by a faulty method of using the voice; a callus occasioned by attrition of one band against the other.

(4) Chorditis tuberosa occurs more frequently in women than men and is more often seen on the left than the right band.

(5) A nodular enlargement will, in time, produce a similar change in the second band at the point of contact.

(6) These nodules should be removed as early as possible. Singing should not be allowed until the bands are normal; and faulty methods of using the voice should be proscribed.

DRS. WESTBROOK, DALY, DELAVAN, MACKENZIE and RICE discussed this communication. The opinions expressed were rather unfavorable to the results of treatment; the supposition being that cases of ordinary chronic laryngitis are likely to be mistaken for "chorditis tuberosa," which is rare.

DR. FLETCHER INGALS, of Chicago, read a paper on UNILATERAL PARALYSIS OF THE LATERAL CRICOARYTENOID MUSCLE.

This is a comparatively rare condition, although bilateral paralysis of the adductors of the vocal cords is a common affection. Two cases are communicated in this paper, both following closely surgical operations in the mouth and naso-pharynx, and apparently hysterical, although possibly reflex. The usual symptoms of adductor paralysis were present. There were no other evidences of disease or of hysteria. The first, a school teacher, twenty-two years of age, recovered after a few weeks of mainly constitutional treatment. The second, a girl nineteen years of age, has been under treatment for about four weeks, without perceptible improvement.

DR. BOSWORTH noted one peculiarity of laryngeal paralysis. In several cases he had seen paralysis of one side of the larynx, with complete loss of voice, and in two instances, with production of falsetto voice. At the end of three or four weeks, the voice became almost absolutely normal, while the paralysis persisted; the unaffected band having swung over to meet the paralyzed one, and so restored the voice.

DR. FRANK BOSWORTH, of New York, reported

A CASE OF UNILATERAL PARALYSIS OF THE ABDUCTORS OF THE LARYNX; THE RESULT OF AN ATTACK OF BULBAR DISEASE; WITH UNUSUAL SYMPTOMS.

A gentleman, who had chronic suppurative inflammation of left antrum following ulceration around a tooth which had been extracted nine months before coming under observation, gave the following history:

He had an attack during the night of dizziness and nausea followed by right hemiplegia, with lateral loss of taste, and difficulty in deglutition. This attack passed away, and four months later, when seen, considered himself completely recovered from the attack. No paralysis of extremities. Right vocal cord was motionless, however. This was due to some permanent change in the centre in the medulla governing the motions of the abductor muscle of the right side. A second case was referred to, which had been pronounced one of paralysis of left abductor, due to aneurism. Upon examination, a partial ankylosis of the crico-arytenoid was discovered, which fully accounted for the symptoms present. Here was a case pronounced one of paralysis by a very competent observer, and yet one which should not be regarded as either extrinsic, myopathic or any other form of paralysis.

An inquiry from DR. WESTBROOK if the suddenness of onset, and the extent of motor paralysis, and short duration would not exclude the medulla as the site of the lesion, and favor the view of embolism involving the capsule, brought the reply that there was no doubt in the reader's mind that the case was one of bulbar paralysis, which might have been due to a clot or some lesion involving the base of the brain or the cerebellum.

The third day's session, held in the Library of the Johns Hopkins Hospital, began, at 11 A.M., with a paper by DR. D. BRYSON DELAVAN, of New York,
ON THE EARLY DIAGNOSIS OF MALIGNANT DISEASE
OF THE LARYNX.

The lecturer dwelt upon the great importance of an early diagnosis of carcinoma, and the necessity of prompt recognition of the disease. The diagnosis in many cases is rendered difficult by complications. Thus, pulmonary phthisis may be in active progress, and lead to the diagnosis of tubercular laryngitis. The appearances of syphilitic of the larynx are often like those of cancer, and the temporary improvement, often seen under the influence of iodide of potassium, still further misleads the observer. On the other hand, syphilis of the larynx is often pronounced cancer, and serious operations advised. From a careful review, he believed that three points in diagnosis may be useful early in the case:

(1) Thickening of the mucous membrane, with marked loss of motion in the neighborhood of such thickening, implies an infiltration of the muscles which, generally speaking, is due to malignant disease. An apparent paralysis of one side of the larynx, associated with thickening upon the same side, should always call for the exercise of extreme caution in the matter of prognosis.

(2) As the result of numerous investigations made by many observers during the past two years, it is generally admitted that, of new growths of the larynx apparently papillomatous, those, the bases of which are not surrounded by a zone of inflammation, are probably benign; while those which are encircled by a ring of reddened, infiltrated membrane are almost certain to be malignant. The truth of this proposition has been verified in several instances by the writer.

Trans-illumination of the larynx, first suggested by Voltolini, has been studied during the past year by several observers. While by the use of the electric light, applied to the exterior of the larynx, the writer has

found it possible to gain tolerably satisfactory results in causing the light to penetrate the walls of the larynx, it would hardly be possible by this method to recognize the presence of an abnormal thickening, which was not already sufficiently well-developed, to be visible to the eye by the ordinary intra-laryngeal demonstration. As a means of recognizing the presence of a new growth of recent origin and of small extent, this method is, at present, of doubtful value. For the purpose, however, of demonstrating the relative density of an enlargement of appreciable size, trans-illumination of the larynx is a method of considerable importance, and, even in cases of the class first mentioned, it may occasionally be found useful.

DRS. MACKENZIE, DALY, INGALS, BOSWORTH, HOLDEN, ASCH, MULHALL, SWAIN, LANGMAID, SEILER and DELAVAN participated in a lengthy discussion, in which there was little disposition to accept any diagnostic character of early carcinoma. Dr. Langmaid mentioned a zone of infiltration and redness of the tissue around the growth as an early indication of its malignant nature. The treatment was thoroughly discussed.

A paper by DR. GEO. W. MAJOR entitled

NOTES ON AN INTERESTING CASE OF ANEURISM,
read by title, and referred for publication.

DR. JOHN O. ROE, of Rochester, N. Y., reported and showed photographs of the post-mortem appearances of

A CASE OF STRICTURE OF THE ESOPHAGUS FROM
INTERSTITIAL THICKENING OF ITS WALLS,
which he considered a fibroid hypertrophy.

The case was a woman, fifty-eight years of age, free from syphilitic history. The patient died from exhaustion. On post-mortem examination, ankylosis of the arytenoid articulations was found, which had been diagnosed during life; also a marked rigidity of the wall of the larynx due to general thickening of the tissues throughout the larynx. No indication of tubercle. Several constrictions were found in the esophagus, only admitting a lead pencil by using force. Microscopic examination of the thickened walls showed a connective tissue infiltration, the muscular fibrilla being degenerated and replaced by this connective tissue formation. It was, therefore, a pseudo-hypertrophy of the muscular wall, but a real hypertrophy of the connective tissue. The new formation was attributed to chronic inflammation analogous to that in the lungs in fibroid phthisis.

DR. LANGMAID inquired if the lecturer had tried the introduction of a permanent tube in the esophagus?

DR. ROE: It was tried, but the patient could not endure it.

DR. MULHALL: Was ankylosis of crico-arytenoid articulation first detected post-mortem?

DR. ROE: No, it was discovered by the laryngoscope during life. The patient spoke in a monotone without modulation of voice, same as in paralysis of the posterior crico-arytenoid muscle.

DR. MULHALL: Was there not paralysis?

DR. ROE: Yes, from pressure.

DR. BOSWORTH: There could not be a better illustration of the fact that all cases of immobility of portions of the larynx are not always due to paralysis; here there was ankylosis. The pressure upon the recurrent laryngeal nerve had nothing to do with the paralysis.

DR. ROE stated that he had said that the ankylosis might have antedated the paralysis, but did not say that it had.

DR. MULHALL said that he had made two post-mortem examinations of malignant disease involving the recurrent laryngeal nerve, and in both cases the larynx was in the cadaveric position. In neither case was there the least ankylosis of the crico-arytenoid joint, although it had been immobilized for months. This is why he asked the question. Does Dr. Roe think that the ankylosis of this joint was the cause of the appearance in the larynx?

DR. ROE: No. There was sufficient infiltration of tissues in the larynx to account for it.

DR. MULHALL inquired if he thought that an abductor paralysis of eight or nine months, with very little motion, if any, in this joint, would produce ankylosis?

DR. BOSWORTH: A case was reported by Lefferts, in which, paralysis was due to a gumma; months afterward the gumma was absorbed, and the mobility of the joint was restored. Why should there be loss of motion?

DR. ROE: There was every evidence in this case, that there was complete paralysis of the larynx, so that this pressure upon the laryngeal nerve, and this infiltration of tissue occurred before ankylosis took place. The paralysis of the posterior crico-arytenoid might have taken place first before complete paralysis. In another case with paralysis of both posterior crico-arytenoids; and on post-mortem examination, the original cause was found to be a clot in the brain.

DR. BOSWORTH: It is an interesting communication, and recalls the famous case of Mackenzie's.

DR. MULHALL: Was the patient iodized?

DR. ROE: Yes. She had been treated by iodide of potassium; but when she came under observation, she was dying from exhaustion, and only lived a few days.

A paper by DR. F. DONALDSON entitled

THE LARYNGOLOGY OF TROUSSEAU AND HORACE GREEN,

by request of the author, was read by title.

In executive session, the following officers were elected for the ensuing year: W. C. Glasgow, M.D., of St. Louis, President; J. O. Roe, M.D., of Rochester, Vice-President; J. H. Hartman, M.D., of Baltimore, Second Vice-President; Charles H. Knight, M.D., of New York, Secretary and Treasurer; Thomas R. French, M.D., of Brooklyn, N. Y., Librarian; Harrison Allen, M.D., of Philadelphia, Member of Council.

The next place of meeting, Washington, D. C., with the triennial Congress of American Physicians, 1891.

AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.¹

SECOND DAY.—JUNE 4TH, 1890.
AFTERNOON SESSION.

NOTES ON THE OPERATION, AFTER-TREATMENT, AND RESULTS OF LITHOLAPAXY,

by DR. G. CHISMORE, San Francisco, Cal.

A MEMORANDUM IN A RARE COMPLICATION IN LITHOLAPAXY,

by DR. J. WILLIAM WHITE, Philadelphia, Pa.

¹ Report of the Fourth Annual Meeting, at Altoona, Pa. Concluded from page 17 of the Journal.

Patient aged forty, weight 270 pounds, frequent urination, sometimes occasional sudden stoppage of stream in the act. Examination showed small stone in the bladder, moderately enlarged prostate, contracted meatus, hyperesthetic urethra, granular and hyaline casts in urine. Patient etherized; bladder washed out, four or five ounces of boric-acid solution left in. Lithotrite easily introduced; the stone which was not over one-half inch in diameter caught, broken, and two of the fragments seized and further broken. On withdrawing the lithotrite, a gush of fluid followed the instrument. Attempting to insert a small, evacuating-tube, it was arrested at the prostate and would pass no further. All the instruments tried likewise failed. Forced injections of oil, urethral forceps, etc., were tried perseveringly. A large, blunt instrument was used in the effort of forcing this supposed fragment back into the bladder, but without avail. Finally, a small Nelaton catheter passed into the bladder. For a few days considerable difficulty in urination; smallness, deviation of stream, and much tenesmus. On the fourth day, while straining, he ejected a uric-acid stone, after which urination was much easier and symptoms disappeared. Lithotrite again introduced, and a small fragment crushed. Patient in a few days returned home.

DR. W. K. ORIS thought it a mistake to operate with cocaine. Bladders which had held a stone some time were exceedingly tender, and the continual straining of the patient in the effort to expel the contents of the bladder made it difficult to operate. While cocaine dulled the sensation in the urethra, it did not dull the sensation in the bladder very much because the bladder was not very absorptive. In regard to Dr. White's case, he had seen that accident happen several times, but had finally succeeded in passing a smaller lithotrite.

DR. BANGS had only once had an impacted fragment like the one described by Dr. White. He called attention to one of the causes of failure of litholapaxy; namely, when the stone was encysted.

DR. CABOT said the accident mentioned by Dr. White had not occurred in his experience, but he had seen it occur, in one case with fatal result. Dr. Chismore spoke of the difficulty of getting the last fragment or getting the stone at all in some cases where there was a pocket behind the prostate. In the extreme case described that might be possible. He had found where the pocket was of less importance than in that case, the position of the patient to help very materially in getting the stone. By raising the hips so as to roll the stone back from the prostate to the fundus of the bladder, one could often easily reach a stone which before was inaccessible. He had several times used Dr. Chismore's suction lithotrite, and had found it of value in searching for a fragment he had failed to seize with the lithotrite.

DR. BRYSON was surprised that no mention had been made of the use of the cystoscope in a case where there was doubt as to whether a fragment still remained. He thought by the use of it a good deal could be told about the pockets in the bladder, unless there was considerable bleeding. Dr. Bryson mentioned an experience similar to the one Dr. White had had. He had oftentimes been embarrassed in the removal of fragments with any apparatus owing to the thickness and toughness of the mucus in which these fragments of secondary calculi were often imbedded.

A mixture of bicarbonate of sodium would dissolve the mucus better than anything else he knew of.

A CASE OF CYST OF THE KIDNEY APPARENTLY CURED BY A SINGLE ASPIRATION,

by DR. A. T. CABOT, Boston.

DR. J. W. WHITE was not aware that authorities were so positively in favor of nephrectomy under such circumstances. It never would have occurred to him in a simple case of hydronephrosis or simple cyst of the kidney to do nephrectomy without first trying the effects of nephromy. Statistics showed that nephrectomies after nephrotomies were less fatal than primary nephrectomies.

DR. BRYSON agreed with Dr. White that it would not occur to him to do a nephrectomy first under such circumstances. He thought that in every case there was ample time for drainage. He did not think the danger to the general health was sufficiently severe to warrant measures being taken with any degree of speed.

PERIPHERAL NEURITIS OF SYPHILITIC ORIGIN,

by DR. J. A. FORDYCE, New York

The writer spoke of the infrequency with which inflammation of the peripheral nerves was encountered in syphilis, and reported two cases which had come under his observation. In one patient four months after infection, a paralysis of the facial nerve occurred, involving both the eye and the mouth muscles, and slightly impairing the sense of taste on the paralysed side. The paralysis disappeared at the end of two weeks under antisiphilitic treatment.

In the second case reported, a multiple neuritis of the lower extremities appeared with the outbreak of the early secondary eruption. The affection was characterized by paresis of the lower extremities, inability of the patient to walk or stand erect, loss of the patellar tendon reflexes, muscular tenderness, and numbness of the feet and lower one-third of the legs. Electrical examination showed loss of excitability of the nerves, and partial reaction of degeneration in the muscles, together with muscular atrophy. The functions of the bladder and rectum were unimpaired. The patient recovered the use of his lower extremities under the use of mercurial inunctions and iodide of potassium.

A CONTRIBUTION TO THE STUDY OF MULTIPLE NEURITIS OF SYPHILITIC ORIGIN,

by R. W. TAYLOR, New York.

DR. POST said that Dr. Taylor's last remark in regard to the evanescence of the analgesia brought to his mind a case of his in which a gentleman who has had syphilis of some ten years' duration has on one thigh an analgesic spot which has existed since a very early time in his syphilis, and has not changed from the first. There certainly could be no hysteria in that case.

DR. R. W. TAYLOR said there was one point he had not elaborated as yet; namely, that frictions of mercurial ointment caused subsidence of the swellings and disappearance of the pain. He thought the affection might be summed up in this way: that it was a process analogous to that which goes on in the fibrous tissues of the joints, which was inflammatory and hyperplastic and produced those arthralgias, that is, a simple, inflammatory process taking place in the connective tissues of the nerve, irritating that and caus-

ing pain, or being of a less hyperplastic, less inflammatory character, and going on to the degeneration of the nerve.

DIPHTHERIA OF THE MEATUS URINARIUS.

by DR. F. TILDEN BROWN, New York.

Young man, nineteen; healthy. Dirty household cotton used by the patient to cover the glans. Infection rapidly developed within thirty-six hours. When next seen, presented a raised-up, wax-like formation over the meatus, which microscopically showed cocci, diplococci, streptococci, besides three varieties of bacilli. For the next three days, newly formed caps were removed with increasing difficulty. Finally, necrotic action resulted in the loss of the tip of the glans and contraction of the meatus. Constitutional symptoms slight, but pretty clearly brought out by the advent, short continuance, total disappearance of albuminuria, with certain renal elements shown microscopically. Recovery complete, without extension of diphtheritic process along the urinary tract.

DR. TAYLOR had seen many such cases following circumcision, particularly in those who lived in squalor and poverty. The glans penis was attacked with redness of an exudative character, and was promptly covered over with this dirty-colored membrane, which in its first stages had the appearance of tallow. As that increased, it dried into this tough, brownish-white membrane. He had seen the same diphtheritic condition on the healing surface of chancres.

A CASE OF EXTRHOPE OF THE BLADDER (WITH PHOTOGRAPHS),

by DR. A. T. CABOT, Boston.

Boy of five; well-nourished. Congenital exstrophy of the bladder and epispadias; defect in anterior abdominal wall perhaps three-fourths of an inch in diameter; and, as usual, the whole upper wall of urethra wanting. Abdominal wall lax. Decided to operate by parting the skin at a short distance around the defect, and then bringing it together with sutures, so that the under surface of the fold thus formed should be the anterior wall of the bladder. Operation, July, 1889. The epithelial covering of the surface immediately around the opening was very thin and closely attached to the tissues beneath. A line about one-half an inch wide was denuded at a sufficient distance from the edge of where the tissues were lax and could slide easily on the underlying parts. The only place where there was any difficulty in bringing the sides together was at the upper angle, where there was considerable scar-like tissue, the remains of the umbilical scar. This upper portion which came together hard, failed of union; but all of the lower part healed by first intention, and formed a bridge over the opening in the abdominal wall which prevented any considerable prolapse of the bladder mucous membrane. The opening between this bridge and the upper surface of the penis was so close that the escape of urine was much interfered with, and in consequence a considerable hydronephrosis formed; and during this time the boy became very weak and pale, and the amount of urine was considerably diminished. October 22d, second operation for providing a more free escape of urine. Body of penis removed; mucous membrane of urethra dissected off, and united to prepuce. Urine escaped much more freely. Boy rapidly recovered.

DR. BRYSON said that in case of deformities of the lower genital or urinary organs, we were apt to find deformities elsewhere, that is, hypospadias or undescended testicle, as a rule, indicated that there were other deformities, and he had wondered if that could possibly have anything to do with hydronephrosis.

DR. CABOT stated that the hydronephrotic condition came on very slowly.

A METHOD OF EMPLOYING ANTISEPSIS IN RECENT ANTERIOR URETHRITIS,

by DR. J. W. WHITE, Philadelphia, Pa.

Dr. White had used salol combined with cubeps and copaiba in tablets in about ninety cases of gonorrhœa. These cases were not selected, but were taken as they presented themselves. The amount of salol given was at first about four grains, six times a day. Later, the amount was increased. This treatment seemed to him to yield better results than cubeps and copaiba alone and indeed better than any form of treatment hitherto used by him. He merely wished to state his impression of the value of salol in gonorrhœa after a limited experience both in respect to time and number of cases.

DR. R. W. TAYLOR said the only tangible evidence that the gonococcus was the etiological factor in gonorrhœa rested upon the experiment of Bumm, who had inoculated the urethra of a woman with the twentieth culture of the gonococcus, and produced the disease; but the details of the environment of the case were not such as to make it certain that the gonorrhœa arose in its way. He did not deny that gonorrhœa might be the result of the gonococcus, but there was no proof of it other than that cited. The micro-organism theory was elusive in practice. He had found no good at all from retro-injections, or from injections of bichloride of mercury, in gonorrhœa. He did not think one could draw definite conclusions as to the efficacy of salol in this disease, so long as it was used in combination with other drugs like cubeps and copaiba. Time was also a very important element in testing a drug.

DR. BELFIELD thought Dr. White had taken a very rational position in the matter. In estimating the value of any drug in the treatment of gonorrhœa, we must bear in mind that the disease is often very closely simulated by something which is not gonorrhœa. A man who had had gonorrhœa might have an outbreak which closely resembled the genuine outbreak; and the clinical course of this would be much more favorable, whatever the therapeutics employed, than in case of a fresh infection of a virgin urethra. He believed gonorrhœa to be a parasitic disease, yet all the remedies which destroyed parasites had been unavailing in his hands, and he employed the purely empirical treatment of hydrastis locally, and an alkali. He had had no experience with the combination used by Dr. White. The fact that in any given urethra about one-half of the lacunæ opened backward was, as Dr. White had suggested, an important factor in the persistence and recurrence of gonorrhœa. The lacunæ which opened backward formed a nidus for the reception of gonorrhœal poison.

DR. F. T. BROWN said he was so thoroughly satisfied as to the position of Neisser, that he did all his work on the presumption that his statements were going to hold good. He had relied upon the Lafayette mixture, with the employment locally of bichlor-

ride retro-injections (1-30,000 to 1-15,000). After a week's use, he had generally combined a weak solution of nitrate of silver (1-1,000 or 1-2,000).

DR. J. B. WHITTE agreed with Dr. Taylor, that a specific cause of gonorrhœa was not proven, yet he thought the preponderance of evidence was to the effect that gonorrhœa was a specific disease. He had not seen satisfactory results from deep urethral injections. He had sometimes seen considerable urethrovaginal irritation occasioned by it. He had not had satisfactory results from the use of the bichloride solution, either in the mild or strong solution. He had obtained better results from simply washing out the urethra with warm water, and then injecting a mild hot solution of sulphate of zinc. As a rule, he did not give any internal treatment unless the symptoms required it.

DR. J. A. FORDYCE had used in 150 or 200 outpatients of the Bellevue Hospital a solution of nitrate of silver, about 1 to 4,000. This gave rise in some cases to bloody urine; in others, to great pain in urination, so that treatment had to be suspended or the solution made weaker. In some cases in which the nitrate of silver caused much pain, he gave the Lafayette mixture internally. He thought he got better results from this solution than from the ordinary injections, and felt disposed to continue its use.

DR. POST thought, in testing new remedies, first cases of gonorrhœa were the only ones that should be considered. He was surprised that so little value had been placed on the oil of sandalwood which he regarded the best of antibenorrhagics. It certainly was equal in efficacy upon the gonorrhœa with copaiba, and much less likely to overturn the stomach. His favorite injection was a very dilute solution of bichloride of mercury. He did not use injections during the acute, inflammatory stage.

DR. W. K. OTIS thought salol, if efficacious, a particularly good remedy, because, while giving that, it would not be necessary to give injections. If one believed in the gonococcus, one would not give injections in the acute stage, because the gonococcus was then out of the reach of injections, and one also took the risk of causing a posterior urethritis by washing the pus down the urethra. In case of fresh gonorrhœa, he thought recovery in six weeks was doing well. He was using injections of the nitrate of silver. Patients bore it well, as strong as 1 to 1,000.

DR. D. R. PALMER believed in the gonococcus and in the antisepctic treatment of gonorrhœa. He had had some very favorable experience in the matter of irrigation. This he applied with the culver nozzle rather than with the catheter. He believed we had not introduced all the medicaments that could possibly be of any benefit in the way of direct local application, and that the solution of the problem lay largely in internal medication. There had been an era of internal medication in the past, but that was a blind one compared to this. There were the same objections to internal treatment as to local treatment: the remedies used were liable to cause disturbance. Salol did not disturb the stomach, and should be given up to fifteen grains three times a day. He was surprised to hear the statements as to the strength of nitrate of silver solutions used. He began, in acute cases, with a little citrate of potash internally, and hot applications. As soon as it could be borne, he used bichloride of mercury, the strength of the wash being determined by

the sensitiveness of the urethra. A four per cent. solution of cocaine would relieve the sensitiveness, if it were great. He used the boric-acid injection for its soothing effect. In the stage of decline he used an injection of nitrate of silver, five to seven and one-half grains to the ounce. This injection was carried down fully six inches by means of the long solid-silver nozzle. If the patient complained of pain, he used cocaine. Such injections were given two or three times a week. Sometimes hot, boric-acid injections were used after them, and the patient was allowed to use at home any of the old injections. In short, he attempted to fight the disease "horse, foot and dragoons"; care being observed not to set up inflammatory trouble and tumefaction.

DR. GLENN said that during the last five years he had obtained good results from the use of weak, non-irritating injections of chloride and iodide of zinc, — iodide of zinc ten grains, chloride of zinc three grains, water six ounces, long syringe with good nozzle. He used it at any stage that the patient would endure it.

DR. L. B. BANGS said he had no routine treatment. He tried to overcome hyperaemia by rest in bed. He did not use bichloride injections. If he used bichloride irrigations it was to secure good drainage and soothe the mucous membrane.

DR. J. P. BRYSON alluded to a paper written by DR. BRYAN and himself, which was based on the observation of 1,394 cases of gonorrhœa observed tolerably carefully at the clinique. It gave the amplest possible clinical confirmation of the specificity of gonorrhœa and also of the assertion that the micrococcus of *Neisser* was the specific element in the production of the disease. The paper dwelt also upon two points connected with the internal administration of remedies: (1) the sterilization of the urine; (2) all those remedies which acted through the urine also acted, and, as he thought, more directly and thoroughly upon the gonococcus through the blood. His opinions were fully expressed in that paper, and had not in any way changed.

DR. J. W. WHITE said that he had seen exceeding severe irritation set up by an injection of nitrate of silver as strong as five to seven grains to the ounce of water, and also that he was afraid of urethral injections of cocaine.

AMERICAN NEUROLOGICAL ASSOCIATION.

The Sixteenth Annual Meeting was held in the Hall of the College of Physicians, Philadelphia, June 4, 5 and 6, 1890.

The President, DR. E. C. SPITZER, on calling the meeting to order for the business of the opening session said that though there might have been in the history of the society a period when it had devolved upon the presiding officer to fill gaps in the programme, this was no longer the case; and with such a plethora of scientific papers as confronted them, communications by the President might well, at this stage be omitted. He should like to thank the local neurological society for its courtesy and exertions on behalf of the national body. He would call attention to a very beautiful specimen of

MULTIPLE THROMBI OF THE CIRCLE OF WILLIS, prepared for their inspection. The patient from whom this was taken had been attacked by incomplete

left hemiplegia. The facial portion had remained stationary while the rest had improved. Then there had been another attack, involving the other side with parasthesia and pain. The case had terminated in coma and death soon after the second seizure.

UNUSUAL FORMS OF CHOREA, POSSIBLY OF SPINAL ORIGIN.

This was the title of a joint communication by DR. S. WEIR MITCHELL, and C. W. BURR.

The first case described was one of inherited, congenital chorea, possibly involving the spinal cord. The patient, a young man eighteen years of age, had presented himself at Dr. Mitchell's clinic in 1889, complaining of constant, involuntary movements of the legs, arms and head. The history of the patient's family was of special interest in this case.

His maternal grandmother had suffered from chorea for many years, not from birth; but she had while so affected given birth to the patient's mother, who was choreic from birth till death. Both the patient's parents had died of phthisis. There was no history of other cases of chorea or any nervous disease in the family. The patient's choreic movements had begun in early infancy, probably from birth, and as a child he was puny, and of tardy development. His present condition was that of a fairly built young man, of good strength, weighing one hundred and thirty pounds, and other than the condition immediately associated with the chorea, there was no physiological disturbance. Knee-jerk was increased on both sides, and the cremasteric, sole and abdominal reflexes were marked; ankle clonus was occasionally present, and at times rigidity at the knee, the feet being then turned inward at the ankle. All the conditions were increased by motion, and the administration of moderate doses of strychnia. Sensation to touch, pain and temperature were normal, and so was station. While awake the patient's entire voluntary muscular system was more or less in action. Sudden presence of a stranger emphasized the trouble. During sleep there was perfect quiet. No spinal tenderness existed; urine was normal; and so, with some slight muscular insufficiency excepted, was vision.

Dr. Mitchell then read in detail two other cases, in which the patients were brothers, their father having at forty-five years of age developed alleged choreic symptoms. The first of these two cases had resembled in general aspect canine chorea.

The authors of the paper thought the first of the series of three cases in which the disease had run through three generations, extremely rare and that organic changes were present somewhere in the motor tract of the patient might, they thought, be admitted, because of the extreme chronicity of the affection, its resistance to all treatment, and the presence of very distinct ankle-clonus and rigidity, these latter symptoms pointing to involvement of the cord. Whether the changes were confined to the cord it was more difficult to say. It was not wished to do more than indicate the spine as possibly implicated in all the cases.

DR. C. L. DANA, said he thought the view taken by Dr. Mitchell, as to the relation of heredity in chorea was the correct one.

DR. SACHS, suggested that some of the features Dr. Mitchell had mentioned in detailing his cases of chorea resembled somewhat the peculiar disorders of movement noticed in children with spastic palsies.

Some of these conditions appeared at a late date, and might be either mild or severe in character.

DR. MITCHELL said the view he had advanced was rather an hypothesis than a theory.

DR. SACHS said that he had seen these peculiar disorders present after every trace of the early paralysis had disappeared. In two of the cases cited, the patient had shown exaggerated reflexes which were also found in the congenital case, it was possible that one or other of the cases might be congenital palsy, in which the symptoms of palsy had disappeared. He could not abandon the idea that some of the cases described might show changes in some part of the brain.

DR. E. D. FISHER stated that he had seen a great many such cases as Dr. Sachs had referred to. In the almshouse they had both adults and children whose history was that of congenital paraplegia or hemiplegia of cerebral origin, and in which the paralyses were associated with well-marked choreic movements. It had seemed to the speaker that many of these cases where the condition had remained chronic for so long a time, were really not of the nature of ordinary chorea, which was a self-limited disease. He had always regarded these conditions as associated with sclerosis, leading to degeneration in the nerve-cells and nerve-fibres, and to descending degeneration in the cord. He had looked upon this as of cerebral origin, because it was found that the mental powers, though not greatly affected, showed some dulness, especially in the acquisition of knowledge.

DR. F. X. DERCUM thought it was not at all improbable that a spinal centre might be affected. No doubt there was a form which was purely spinal.

DR. WEIR MITCHELL said that many years ago he had stated his belief that ordinary chorea should be classified into three distinct groups. It was true that cerebral changes could arise in these choreic conditions, but it was rare to see these conditions affecting both sides, no matter what the changes were in the brain. Trouble in both lower extremities was especially rare; therefore the first case alluded to was not choreic, resulting originally from paralytic conditions accompanied by descending degeneration of the cord.

DOUBLE CONSCIOUSNESS.

Dr. Mitchell then alluded to the notorious case of Ansell Brown, who had left his home, assumed another name, and, as asserted, had lived for some time without knowledge of his previous existence. On regaining control of his proper identity, he had returned home. Hypnotism had been recently tried upon him, and while under its influence the man's mind could be made to revert to incidents in his fictitious existence, while of his real identity he would then know nothing.

DR. KNAPP cited a case of hystero-epilepsy, in which there were decided spells of changed consciousness. As to the question of spinal chorea, he was struck with the analogy of Sydenham's chorea with the conditions of ataxia, tonic spasm and associated movements of which he had recorded several cases, and to which some of these cases of chorea bore striking resemblance. It did not seem, however, that we were yet in a position to assume any one of these motor disturbances as having focal significance. They might have their origin anywhere within the motor tract, and he hoped to show that tumors were not unfrequently the cause.

THE WEATHER IN RELATION TO NEURALGIC PAIN.

DR. MITCHELL had had an intelligent patient of his, who was a great sufferer from neuralgic attacks, make elaborate studies and observations of the effect of variations of the weather upon the paroxysms. Briefly stated, the scientific findings were that the maximum of pain bore direct proportion to the prevalence of storms, and that the Aurora was a certain precursor of neuralgic exacerbation.

CHRONIC SOFTENING OF THE CORD.—SENILE PARAPLEGIA.

DR. C. L. DANA, of New York, read a paper on this subject, narrating a case which, he said, established upon firm foundation, for the first time, the fact that in the gray matter of the cord, there might exist progressive softening from obliterating arteritis, just as found in the brain. It also established the pathology of senile paraplegia, no convincing evidence as to the nature of which had, until recently, been adduced. The question of non-inflammatory softening of the cord had been but obscurely dealt with, or let entirely alone. Acute softening had been described usually as synonymous with acute myelitis, but the term was wrongly used, and should not be applied to inflammatory processes at all. It had of late been suggested that some of the cases of acute myelitis were, in fact, primarily necrotic processes, but evidence was lacking in substantiation. The case he would describe was not of the acute type, but was a chronic myelomalacia.

The patient, an old man of seventy years of age, of whose early life little could be elicited, except that he had been generally healthy, had, about four years ago, noticed some weakness of the legs. There was no pain. The condition had progressed, until one year ago there was complete disability to walk, incontinence of urine, and trouble with the rectal sphincters. When seen in 1889, the man had presented the characteristic appearances of senility. The symptoms of the disease were limited to the lower extremities, which were wasted and contractured, and knee-jerks were gone, there was no clonus or trepidation. Sensation was everywhere normal, indeed the condition was rather that of hyperesthesia. No pains in the legs, girdle pains or bedsores. Up to the time of the patient's death, which had resulted immediately from exhaustion, the general symptoms had changed but little. The mind was clear, though senile. The only gross changes in the cord or membranes was noticed in the anterior horns in the sections taken low down. The more minute examination of microscopical sections had demonstrated the case as one of degenerative endarteritis with sclerosis, obliteration of the vessels, causing the softening of the anterior horns and intermediate gray matter. This process was accompanied by secondary congestion, dilatation of small vessels and capillaries, but no hemorrhages. The condition was one of softening of the cord precisely analogous to the so-called softening of the brain. It was not inflammatory, and could not be termed an anterior polio-myelitis. It was not cell atrophy, and did not belong to the spinal forms of progressive muscular atrophy. While the change was, without doubt, largely a senile one, the cord did not correspond to the description of such conditions given by Leyden. The disease might be called a senile paraplegia from softening of the anterior horns due to obliterating arteritis.

(To be continued.)

THE COUNTRY DOCTOR.

WONDER has often been expressed that the country doctor — and we make this remark knowing that there are illustrious exceptions — has not done more to advance medicine. He writes but little, makes few original investigations, and now that preliminary study with a preceptor, is growing less and less acceptable to medical schools, influences slightly professional opinion. We allude particularly (and we wish in what we say to be so understood) to the practitioner whose home is far from the metropolis, the medical school and hospital, who seldom finds time to get away for a day's vacation to attend clinics, witness a major operation, or even be present at an important medical meeting. He possibly takes one medical journal, or he may long since have given this up, "not having time to read it." He has frequent cases which he has carefully followed to their termination, and where he has been generously granted an autopsy; these cases, which would be instructive if reported, he has never written out; in fact, writing is irksome to him, and he has no incentive to contribute new data to science. It has not been his custom to take daily notes of his cases. He makes few changes in his practice, except as occasionally a consultation with some younger physician, fresh from clinics and hospital work, reminds him that methods and manners are changing. Now and then some old professor from the great Hospital Medical School comes into his section of the country for recreation, for hunting or fishing, and "posts him up" as to modern methods.

The country physician is both conservative and cautious. He is very shy of the new remedies. He would not dare to open the knee-joint antisepically and drain it for a traumatic arthritis, much less perform a resection, or laparotomy; if those operations are required, his metropolitan brother must be summoned. This timidity is not to be wondered at, it is so seldom that he sees cases requiring peculiar surgical skill. An ordinary amputation he does not fear; he gives his anesthetic and goes to work with a farm-hand for

his assistant; he makes his flaps *secundum artem*, dexterously takes up and ligatures the arteries, and puts on the dressing; thanks to healthy surroundings and good air, the operation is a success though done without antiseptics. As for the treatment of fractures, with his extemporized splints of clapboard, sole leather or glue, he claims as good results as his city brother. And it is an open question whether the city brethren could do as well if placed in the same circumstances.

In regard to the pharmaceutical part of his work, he labors under some disadvantages. There may be no apothecary in the village where he lives and he is obliged to furnish medicines. Consequently he must carry ample supplies with him of *tinct. ferri chloridi*, *pot. nitras.*, *pulv. Doveri*, *quinia sulphas*, *tinctura digitalis*, and various cathartics, diaphoretics and tonics. He has not been "pestered" (we use a term which is current among certain urban medical practitioners) with visits by the pharmaceutical travelling agents with their handsome gelatine-coated pills, their tablet triturates, and their "parvules," consequently the few remedies which he carries are in a rather crude shape.

The country doctor is still somewhat old-fashioned in his therapeutics. He does not hesitate to give tar-tarized antimony in colds and fevers (though in very small doses), but he has long since given up bleeding. Nitrate of potash still serves a variety of uses. He orders Dover's powder and warm wrappings to break up a cold, and has much faith in the liver as the source of all obscure ailments, and in the corrective efficacy of blue pill and black draught. He still treats dyspeptic stomachs with quassia-chip bitters, and if this does no good he gives judicious suggestions as to dieting. Dietetics does not constitute a favorite branch of therapeutics with him, yet experience has taught him many of the simplest and most peremptory rules.

A large part of the country physician's duties is to prescribe for those that are simply "run down," debilitated, suffering from "functional ailments," from cold, overwork, dietary indiscretions; and in treating such patients, he generally brings into exercise the principles of good judgment and common sense. Even if now and then a puzzling case, as of multiple peripheral neuritis, comes before him for diagnosis and treatment, though the diagnosis may be at fault, the treatment may not be altogether harmful.

In the management of children's diseases, the country physician may be somewhat badly off without the multitudinous preparations called "infants' foods," which his city *confrère* possesses, yet with pure cow's milk and flour gruel he gets along fairly well, and sees some cases of intense athresia recover under good hygiene on very simple nourishment, and finds indeed a pleasure in seeing his patients' city grandchildren grow healthy and strong under his care during their summer vacation.

In his obstetric practice, the average country physician, though he uses no antiseptics, has the benefit of pure air, and that is almost everything. He may be a little slow about putting on forceps, but he claims

that time with him is not so precious as to make "meddlesome midwifery" justifiable, and that in "hundreds of cases" he has seldom found the necessity for "interfering with nature's processes," yet for a severe emergency, he is generally equipped and equal.

The country physician deserves high consideration from his fellows, for his lot, if he be a successful practitioner, is a laborious and largely unselfish one; we say unselfish, for no one is more a servant of his constituency than he, and does so much drudgery for so little pay. When his work is done for the day his nights are by no means undisturbed by calls; he is really always tired, and seldom in mood for study or the microscope. His city *confrère*, having his patients near home, can do in a few hours an amount of work that would take the country practitioner all day long, for his patients are often a long distance from home. A drive of ten miles and back over a rough road in the forenoon, and a similar ride in another direction in the afternoon, with other calls sandwiched in, and an obstetric case in the night make considerable draughts on the energy of even the most vigorous man; and when we consider that the country doctor is generally a farmer as well, and think of the social demands on his time (he is often Superintendent of the Sunday School, leader of the "Class Meeting," or the "Prayer Meeting," President of the "Debating Society," or "Literary Club," perhaps "Chairman of the School Board"), we wonder at his powers of endurance and the extent and variety of his labors, and we feel that he rather deserves praise that he is so useful a man rather than blame that he has done so little for medical science.

THE SURGICAL FOURTH.

THE surgery of the Fourth of July is sufficient in itself to justify some forethought on the part of surgeons in the larger places, and presents possibilities not always pleasant to every one engaged in general practice.

The character of such surgery changes from year to year as fashion or progress in the knowledge and manufacture of explosives changes the character of the noise-producing materials. But a few years ago the blank cartridge lodged its wadding in the palm of the hand with wonderful frequency, and lockjaw was by no means an unfrequent sequel of such an accident in various parts of the country.

The deadly toy-pistol, as it was appropriately named by the press, has become less potent as a destructive agent because of the prejudice aroused against it as a dangerous plaything and the recognition of the necessity of caring for its wounds. It has been supplanted by the giant cracker. The pistol reaped its harvest among small boys of about a dozen years of age, more or less. The giant cracker seeks its victim among those boys whose size and years should give them the attributes of men. The results of the cracker are the more or less complete destruction of the hand in which it is held. These crackers are of various sizes designated by numbers, and vary from

those twice or three times the size of the ordinary cracker to those twenty times its size. Occasionally some foolhardy individual will hold one in his hand from a spirit of bravado, occasionally because it is supposed to be a Roman candle, but the majority of injuries are purely accidental. Either the fuse burns faster than was expected and the explosion takes place before the cracker can be dropped, or the cracker fails to explode for so long a time that it is supposed to have gone out, and it is picked up and explodes in the hand.

There is one peculiar feature of these giant-cracker explosions in the hand. In a large proportion of cases the base of the thumb is split open and a compound dislocation produced at the joint of the first metacarpal and the trapezium, so that the thumb and its metacarpal retain their connection with the rest of the hand only by the soft parts, the tip of the thumb being little or not at all injured. If these injuries are carefully cleaned of powder and dirt, they heal as readily as could be expected from the severity of the explosion and the extreme laceration of the wound; but the entire loss of the hand is not unusual. Tetanus is not a frequent result; no single instance of its occurrence after these injuries has occurred in the knowledge of the writer.

The Fourth just passed seems to have been less prolific in injuries than those that have recently preceded it, but it has left much to be desired. There appeared at the Boston City Hospital—the only hospital whose statistics are available at the moment of writing—twenty-one injuries from explosion, of more or less severity. At least seven of them will result in the very great diminution of the usefulness of the hand, though none demanded amputation of the arm.

It would be pleasant to think that the public was awakening to the wanton waste of life and limb our method of celebrating the Fourth incurs.

MEDICAL NOTES.

— Press despatches under date of about July 1st, announced cholera to be on the increase in and about Valencia, and to have broken out in Portugal. Some alarm is felt in London and Paris. In the latter city the government has put to work some 22,000 men at filtering the water-supply.

— The *Christian Union* for June 20th contains an article on "The Advantage of the Woman's College to the Women of America," by Mrs. Alice Freeman Palmer—who, as Miss Alice Freeman, was, until her marriage, the president of Wellesley College. Mrs. Palmer claims that one of the most important influences of the woman's college has been its influence for strong health. "In its robust pleasures and intellectual struggles it has had no place for the interesting invalids of former times. More than any one agency it has contributed to make blooming health expected of women. It has insisted upon regular and simple modes of life. It has founded gymnasiums

and encouraged athletic sports for girls. It has had field and lake and river at the service of its students, and has employed salaried physicians and directors for their safety and guidance. By its varied resources and opportunities it has shown how rich and honorable a thing physical life is, and how well worth maintaining at its highest point of enjoyment and power. All the college women I have known wish to be strong. They rarely confess themselves weak and ailing without an inward sense of shame. They know that lack of self-control — nervousness — is not a necessity even to this hurried and high-strung generation."

NEW ENGLAND.

— Among those who have died of typhoid fever in the recent epidemic in Waterbury, Conn., which is said to have been traced to a milk-supply, was City Engineer Weld, a member of the Waterbury Board of Health, and a practical sanitarian to whom the city is indebted for its system of sewers. This man had labored long and earnestly in defence of the public health so far as the removal of unfavorable conditions within the city limits was concerned; but in the prime of life he has been cut off by poison sent to the city from a farm where the farmer himself lay ill of typhoid fever and from which an employee had recently been taken to the City Hospital, there to die of the same malady.

Miscellany.

A PHYSICIAN'S NOTES IN CENTRAL AFRICA.

We find in the *British Medical Journal* for June 14th, some "Gleanings from the Diary of the Physician in Central Africa," from which we make a short extract relative to certain habits among the Wanyoro, one of the two most powerful tribes inhabiting the fertile lands between Lakes Victoria and Albert.

"When a woman is pregnant and labor commences, all the women of experience are summoned to assist her. She sits on her heels, her knees stretched far apart, while one or two women support her back and arms, and the midwife sits in front of her ready to receive the child. Delivery is promoted by rubbing the uterus. If the head presents it is considered a good sign; if the feet present, it announces misfortune to the family. Should an arm presentation occur, it is replaced and an attempt is made to turn; this operation is performed by men who receive special presents for the service. Should a woman die in childbirth, abdominal section is at once performed, and the child, whether living or dead, removed. Many women die of flooding, probably arising from attempts to remove the placenta. The umbilical cord is cut with a sharp splinter of reed, at a considerable distance from the navel, and is tied to the body of the child until it shrivels or falls off, which is hastened by frequent rubbings with fat. Ligation is quite unknown. The fifth day after birth the mother takes her child and sits with it on the threshold, and the name ceremonies take place. The child is suckled for eighteen months, during which time the mother lives apart from her husband. Many women are barren, and most of them have only two or three children. Unlimited polygamy

is stated to be one of the causes which reduces the population. Unyoro women only bear children between the ages of twelve and twenty-five. A son inherits all his father's wives, who become his wives, with the exception of his own mother. Theft is punished by confiscation of property for the benefit of the person robbed; murder, by the slaying of the murderer by the nearest relatives; and adultery, by the wife being beaten and a fine paid by the offender. Prostitutes are a privileged class, living under the protection of the king, and they are the servants of his wives. Though prostitution exists in all negro countries, it is officially sanctioned only in Unyoro. Private property in land does not exist. The passion for human flesh is hereditary in some families, but cannibalism is practised secretly. These wild tribes are not free from what are often thought to be the diseases of modern life. Epilepsy is common among them, and no cure is known for it. Insanity and also mental aberration are frequent; the latter is treated with herbal remedies, which effect an immediate cure by means of sweating and sleep. Polydactylism is rare; if the superfluous fingers are noticed at birth they are at once removed. Small-pox is much dreaded, and the pustules are opened and washed with warm water, but the sufferers usually die. Vaccination is quite unknown, and syphilis is very prevalent, but widespread disorganization is rare, and there is a tendency to self-healing. The sores are dressed with caustic herbs, and are thereby made worse. Exostosis is common, and its syphilitic origin recognized. The same is true of partial loss of pigment, which is very common in Uganda. Syphilis is said to have been unknown formerly; it has followed in the track of the Nubians."

A CASE IN WHICH CEREBRAL LOCALIZATION WAS ILLUSTRATED BY THE EFFECT OF MENTAL IMPRESSION.

DR. ANDREW H. SMITH reports a case, interesting in the above connection, in the *American Journal of the Medical Sciences* for July, 1890.

"Mr. I. consulted me about three years ago for a condition of the right wrist and hand, from which he had suffered for several years, and which resembled writer's cramp, but differed from that affection etiologically, and in that the condition was one of tremor rather than of spasm. It was not the result of any special or excessive use of the hand, and was associated with a slight degree of paresis of the right leg.

"There was a good deal of occipital pain, which I found to be dependent upon defective action of the ocular muscles. This was completely relieved by prisms selected by Dr. Noyes. Singularly, not only was the pain relieved by the use of the glasses, but the condition of the hand and leg was considerably improved.

"As a great variety of treatment had been tried before I saw the patient, and he had suffered much of many physicians, specialists included, I now advised him to rest content with the measure of relief he had obtained, and to desist from further treatment, diverting his mind as much as possible from his condition by active employment.

"Pursuing this course he has gotten on in the main very well up to the present time. His general health has improved, and the hand and leg are decidedly better. He is, however, still obliged to write with

his left hand, although the right is fairly useful for other purposes.

"This was his condition when, a few days ago, he became interested in reading the article in *Harper's Magazine* for May, in which Mr. Chittenden describes his experience in signing, as Register of the Treasury, 12,500 United States bonds in sixty-four hours, and the physical distress which the effort occasioned. As he progressed in the reading the Mr. I. experienced a severe pain, beginning in the right hand, running up the arm into the neck, then into the occiput, and at last settling with great intensity in a circumscribed spot on the left side of the head. In describing this pain to me he indicated with his finger as accurately as I could possibly have done, the exact situation of the postero-parietal convolution in which Ferrier locates the centre for the wrist and hand of the opposite side. Some pain was also experienced in the leg.

"Now, this gentleman had no knowledge whatever of cerebral localization beyond the broad fact that the brain on one side actuates the muscles on the other. The pain he described could not, therefore, have been the result of suggestion. The conclusion seems inevitable that the phenomena in the hand and leg had back of them a morbid condition of the cortical centre, and that this morbid condition was in such wise influenced by the direction of the mind toward the function of that centre as to express itself in pain. Probably the intermediate link between the mental action and the production of the pain was a vaso-motor disturbance.

"Experiments, especially those of Amidon, indicate that functional activity of a cortical centre may give rise to an appreciable increase of the local temperature. This observation, however, would seem to show that merely occupying the imagination with a function may excite a degree of disturbance in the centre corresponding to that function.

"From a diagnostic point of view, the attack of pain so strangely elicited is important as confirming a cortical origin of the symptoms. From the implication of the leg it is probable that the posterior portion of the convolution was also involved.

"If we accept Ferrier's earlier conclusions as to the function of the angular gyrus in relation to the movements of the eyes, we find in the proximity of this gyrus to the postero-parietal convolution a probable explanation of the improvement in the hand and leg when the eye-strain was relieved. The more recent views, however, as to the location of the centre for ocular movements, remove it so far from this region that this explanation scarcely seems tenable."

A CASE OF ACUTE PANCREATITIS.

THE interest in this class of cases leads us to print the following brief report of a case condensed in the *London Medical Recorder* from the *Wiener Med. Wochensch.*:

The patient, a man aged sixty, was suddenly taken ill with severe vomiting, headache, giddiness and depression. Soon the abdomen began to swell (the next night). There was dyspnea, also painfulness in the left hypochondrium. On reception into the Charité Hospital, a transverse retraction of the abdomen was to be noticed above the navel. Above and below this there was great distension. There was slight fever, with a weak pulse, and a few spots; and typhoid

fever was diagnosed. During six weeks the symptoms altered but little. Towards the end the vomited matter smelt as if decomposed. Within a fortnight afterwards the patient died. The autopsy showed complete necrosis of the pancreas, which lay in a sac formed by the surrounding organs, and containing a thick fluid, with remains of the vessels and some loose fatty tissue. Various openings led into the neighboring intestine. There was extensive necrosis of fatty tissue. The appearances seemed most probably the result of a very acute inflammation of the pancreas."

Correspondence.

A GRAND EXHIBITION OF HYPNOTIZING.

BOSTON, July 7, 1890.

MR. EDITOR:—Gentlemen who have of late been experimenting with a few individual cases in which the phenomena due to "suggestion" are apparently well marked, might find a wider field for investigation in the symptoms due to suggestion, which characterize the grand army (*sic!*) of invalids who are applicants for pensions.

A claim-agent fixes his penetrating glance upon some worthy fellow who gallantly served his country twenty-five years ago. Up to this time, he, the soldier, has been manfully at work supporting his family, unconscious of being the proud possessor of any chronic ailment, although, perhaps, at times he may have realized that a man of fifty or fifty-five years was not quite as spry and active as when he had only the burden of half that number upon his shoulders.

But the mesmeric gaze of the claim-agent brings him into subjection. As he comes under its influence, the suggestion is made after this fashion: "You straighten up slowly when I speak to you? That is due to chronic rheumatism of the back, which you contracted when you were on picket at Mine Run, you remember that you got wet in the swamps. You have pain in your bowels? Yes, of course! The diarrhea that followed eating the mince pies sent you from home at Brandy Station, and which, if it had continued, would have become chronic, has undermined your digestive system and you are a perfect wreck. You are not fit to work any more; go see your local physician and tell him all your symptoms—be sure and tell him all, or even a few more—and ask him if in his opinion they are not all attributable to exposure during your army service. Write to your regimental surgeon for a certificate to the fact of your getting a backache while on picket and the diarrhea during winter quarters. Get a few more certificates from company officers and comrades, then bring them all to me, and I will get you a pension so that you need labor no more."

Once fairly hypnotized, the good fellow comes readily under the influence of friends and pensioned comrades who make similar suggestions. Forced to follow these, the man seeks his local physician, who truthfully tells him that nothing in civil life would produce such a jumble of symptoms, and consequently they must be due to his army experience. The regimental surgeon finds in an old notebook memoranda of the two illnesses, and properly certifies to the facts. The examiner for pensions looks at the evidence, and endeavors to connect the assigned cause with the stated present condition, and honestly (for the man is now really ill by suggestion) passes him; although it may not be exactly clear to him how it came about. Now I maintain that in a considerable proportion of applications for invalid pensions (and I mean those where no fraud is intended), the specific hypnotization practiced by the claim-agent, aided by the generally prevalent impression in the community, that army service must injure a man's health in some way, makes a man really ill. *The man is honest in thinking himself affected with some disease.* A case in point: one of the most straight-forward young

men whom I ever knew, a first-rate non-commissioned officer of the medical department, plucky and honest, came to me in these latter years with the story of failing eyesight, which all of his friends assured him must have had its origin at a time when his regiment was camped in a valley, so situated that the thick smoke from the camp-fires of the corps settled down among the tents for several days, warranting the appellation given it of "Smoky Hollow." I referred him to an eminent oculist, who plainly told him that his sight was good enough for a man of fifty, and that nothing was the matter with his eyes, save the wear and tear of twenty-five years' use since he left the army. In his honest, man-fashioned way, he at once gave up all thought of applying for a pension, although he well knew that others of his comrades had obtained such for no better cause than his.

It seems proper that the medical profession should protest against this manufacture of disease by suggestion. If we must have hypnotism in daily life, let it be remedial, not causative. I am not writing against pensions, I am only setting forth the fact that the pension germ has been a powerful factor in producing disease in that portion of the community who served their country in the field during the late war. I do not keep up with the times in the study of germs, but I think that I am right in stating that this

peculiar germ differs from all others in having no specific function, but can infect any portion of the system, causing any disease in any part from an ingrowing toe-nail to a bald head.

AN OLD ARMY SURGEON.

IODIDE OF SODIUM AND IODIDE OF POTASSIUM.

SALEM, July 3, 1890.

MR. EDITOR:—In the March-April number of *Annales d'Oculistique* is a brief article, signed "W" (presumably Dr. Warlomont), referring to a paper, by Dr. Laborde, on the comparative action of the two above-named salts, which was read before the Paris Academy of Medicine on the 4th of March.

It is an unpleasant surprise to those of us who have prescribed the sodium iodide, because it is more palatable and better borne, apparently, than its displaced isomer, to be informed on high authority that it is almost inert. As to the bromide of sodium, clinical experience in the use of this salt seems to warrant the belief that its action is nearly identical with that of the bromide of potassium.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 28, 1890, TO JULY 4, 1890.

By direction of the Acting Secretary of War, leave of absence for four months is granted Major JAMES P. KIRKALL, surgeon, to take effect when an officer of the Medical Department is assigned by his department commander to relieve him. Par. 6, S. O. 152, A. G. O., July 1, 1890, Washington, D. C.

First Lieutenant ROBERT R. BALL, assistant surgeon, is relieved from duty at Fort Riley, Kansas, and will report in person to the commanding officer, Fort Spokane, Washington, for duty. S. O. 151, Par. 7, A. G. O., June 28, 1890, Washington, D. C.

Captain WILLIAM H. CORBUISIER, assistant surgeon, is relieved from duty at Fort Lewis, Colorado, and will report in person to the commanding officer, Fort Wayne, Michigan, for duty. S. O. 151, Par. 7, A. G. O., June 28, 1890, Washington, D. C.

By direction of the Secretary of War, the following named assistant surgeons (recently appointed) will report in person to the commanding officer of the posts designated opposite their respective names:

First Lieutenant FRANK R. KEEPER, Fort Leavenworth, Kansas.

First Lieutenant THOMAS U. RAYMOND, Fort Sherman, Idaho.

First Lieutenant HENRY D. SNYDER, Fort Reno, Indian Territory.

First Lieutenant ALLEN M. SMITH, Fort Snelling, Minnesota.

First Lieutenant ASHTON H. HEYD, Fort Niobrara, Nebraska.

First Lieutenant JOSEPH P. CLARK, Fort Riley, Kansas.

Par. 6, S. O. 151, A. G. O., June 28, 1890, Washington, D. C.

By direction of the Secretary of War, leave of absence for two months to take effect August 6, 1890, is granted First Lieutenant WILLIAM N. SUTER, assistant surgeon. Par. 3, S. O., June 26, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 5, 1890.

PAGE, J. E., assistant surgeon. Ordered to hospital, Mare Island, Cal.

KENNEDY, R. M., assistant surgeon. Ordered to the League Island Navy Yard, Pa.

OBITUARY. HON. WILLIAM D. PECK, M.D., M.M.S.S.

Dr. William D. Peck, who died at Sterling, Mass., June 29th, had been director of the Boston, Clinton & Fitchburg railroads, and president of the Framingham & Lowell, director of the State Mutual Life Insurance Company of Worcester, director of the Fitchburg National Bank, and president of the Fitchburg Savings Bank. In Sterling for forty-four years he was honored with a continued reelection to the town clerkship, and for thirty-two years he was town treasurer and collector. Dr. Peck's service in the Legislature included three terms in the House and two in the Senate; his law career beginning in 1848, and ending in 1859. Among his classes in the noted class of 1853, Harvard College, were Professor Francis Brown, Professor Joseph Lovering, Professor Henry W. Torrey, and Professor Jeffries Wyman, who all became teachers at their college, and Rev. Dr. George E. Ellis, and Dr. Morrill Wyman. Dr. Peck was born in Cambridge, November 10, 1812, his father being

William Dandridge Peck, the first professor of natural history at Harvard (1805-1822), and his mother being a member of the Hilliard family. The son was much interested in the study of natural history and geology throughout his life. His degree of M.D., was obtained at the Harvard Medical School in 1836, the only surviving members of that class being Oliver Wendell Holmes, Alfred Day, and William Ingalls. His widow and two daughters survive him.

OBITUARY. CHARLES LINNAEUS ALLEN, M.D.

Dr. Charles Linnaeus Allen, died July 24, at Rutland, Vt., of apoplexy. He was born at Brattleboro, June 21, 1820, was graduated from Middlebury College in 1842, and from Castleton Medical College in 1846. He was president of the latter college for several years, and was afterward Professor of Civil and Military Hygiene in the University of Vermont at Burlington. Except during Cleveland's administration, he had been since the War, a member of the Board of Local Pension Examiners. He was Secretary of the State Board of Health, and had been connected with the Board since its organization. He was the first president of the Rutland Medical Club, and a member of the Vermont State Medical Society, the American Medical Association, the American Academy of Medicine, and other societies.

ERRATUM.

In the Journal of June 29th, on page 642, right-hand column, seventh line from bottom, "Dr. Adams, Pittsfield," should read "Dr. Z. B. Adams, Framingham."

Lecture.**INFLUENZA IN MASSACHUSETTS.¹**

BY GEORGE E. SHATTUCK, M.D., OF BOSTON.

THE registration of vital statistics has now been carried on long enough in this Commonwealth, is now sufficiently accurate and is compiled with such care as to make it of great service in any relative study of the past and present of diseases here. The statistics accumulated by the immense extension of life insurance, and the meteorological records of the United States Weather Bureau are other advantages of which the student can make use to-day. So that, notwithstanding the decreasing homogeneity and the increasing density of population, notwithstanding the complexity of pursuits and the exaggerated wear and tear of life, the task of one who seeks to investigate the climate of the Commonwealth and the diseases of its inhabitants is certainly simplified in some important particulars — at least over the time, not so long distant, when the inquirer's main resource was a slow and precarious correspondence by letter with brother practitioners.

INFLUENZA.

Some such thoughts undoubtedly occurred to many when the recent pandemic of influenza swept over the world. It seemed positively churlish to deny hope the impulse to spring once more eternal in the medical breast. With the aid of the telegraph and the submarine cable; of rapid transit by sea and land; of numerous weekly medical publications as well as of the daily press; of the facilities for collective investigation afforded by the frequent meeting of medical societies in Europe and the United States, by the machinery of central bureaus and local boards of health with mortality rates and registration of returns; and above all with the aid of the entirely modern bacteriologist armed with his immersion lens, his culture tubes and his staining preparations — was it not legitimate to hope that, if with the co-operation of all these more or less modern appliances we searched out the secrets of Nature faithfully, we should be able to penetrate a little farther behind her mysteries in this particular disease? Was it not legitimate to trust that we should be able to bequeath to the future something more than we have received from the past, should at least definitely determine some of the doubtful points which presented themselves after the preceding pandemics to puzzle or ensnare the Sydenham Society, and Sir Thomas Watson and Hirsch and other sources of previous wisdom? In short that we should be able to say to our successors something more than that an "influence" coming from we knew not whence, disappearing we knew not whither, and making a large proportion of mankind ill we knew not why, had afflicted the world at a certain date? It is now more than six months since the influenza made its appearance as an epidemic in Western Europe, and more than four months since it ceased to be epidemic in this Commonwealth.

In Berlin, in Munich, and in Paris, Committees of Medical Societies, aided by government, and in London the Local Government Board have been at work upon Collective Investigations of the epidemic; the

¹ Delivered before the Massachusetts Medical Society June 10, 1890. Continued from page 29 of the Journal.

Munich Committee's returns were to be in March 15th, and the Berlin Committee's returns March 21st. The results have not yet reached us, though their probable tenor in each country may be guessed at from the reports of Society meetings, and communications to medical journals, all of which I have reviewed. I have been struck with the reappearance of the same questions arising to perplex observers in turn in all affected regions; with the inevitable tendency to make the disease fit the limited observation of the individual; with repeated proofs of the strength of the temptation to construct a theory upon what passes before one pair of eyes. I even think papers in Medical Journals will show that men who inclined to the explanation of contagion found a larger percentage of enlarged spleens than men who held to the miasmatic theory.

The time which has elapsed is not sufficient for the record and comparison of observations and experiences in different parts of the world; the distance from the preoccupations caused by the rapid succession of crowded days is not sufficient to afford the necessary perspective for so extended a field.

I shall ask your attention then, during the time which remains, to a brief consideration of some points in regard to influenza as exhibited in the last epidemic in Massachusetts. My own interest in the subject is derived from the experience of a large hospital service, of private practice, of personal illness in Boston, and of a general experience in Paris — all within the space of six weeks, from the middle of December, 1889, to February 1, 1890, and of a pretty careful review of the old and recent literature of the subject since the cessation of the epidemic.

So quickly do events succeed each other in our age and so rapidly are the scenes of life shifted, I do not doubt that to some of you the subject seems already old and threadbare. I fear I cannot offer a sure key to any of its mysteries, and I may not tell you anything new, and I may weary you; but I shall, at least, protect myself from a repetition of the comment of an esteemed colleague who, when asked lately about a certain address before a medical meeting, exclaimed: "Oh! you know what it was like, some quotations from Scripture, and not a word about medicine!"

ORIGIN.

Where did the influenza have its origin, where did it come from? Europe first heard of it in Russia, where it was reported as epidemic about the middle of last October — hence it has frequently been spoken of since as the Russian Influenza; — a designation given for the same reason in several previous epidemics. At the same time that influenza exhibited itself in epidemic form at St. Petersburg (60° N. Lat., 30° E. Long.), the middle of October, it was also active at Tomsk, 1,800 miles to the eastward in Siberia (56° N. Lat., 85° E. Long.). A severe epidemic is reported² to have run its course in Bokhara, a district of Chinese Tartary (40° N. Lat., 85° E. Long.), between the end of May and August, 1889. This is really about all the information which we have on the subject of origin up to date. For affording trustworthy epidemiological data the heart of Asia is about what it was in the Middle Ages or at the time of the Garden of Eden, and, although further time for corrected returns

² Prof. Drasche: Wien. Med. Woehen., No. 6, February 8, 1890, p. 219.

from these outlying districts may possibly produce something less vague, the probability is that our successors will learn from us as to the origin of this epidemic what we have learned from our predecessors as to some others — "that it came from the East."

Present information indicates that the *epidemic* began in Berlin, the middle of November; in Hamburg, about the first of December; in Leipzig, about December 10th; in Cologne, December 1st; in Paris, November 26th. (November 26th was the date of the outbreak at the great Louvre Stores.) In Southern Germany, in Austria, in Turkey it was later. In Wurzburg and Munich it began about the middle of December; in Vienna, December 12th; Pesth, December 15th; Belgrade, December 16th; Bucharest and Sophia, December 24th. To the north of Paris, it began at Brussels, December 12th, and Antwerp, December 16th. At London it began the end of December; Madrid, December 14th; Malaga, December 12th; Lisbon, December 21st; Alexandria, December 25th; Cape Town, first week in January.

INFLUENZA IN MASSACHUSETTS.

Our State Board of Health has again justified the position which it has made for itself, by sending out promptly in January circulars to physicians, public institutions, and factories and employers throughout the State, thus providing for a collective investigation of this epidemic within the borders of Massachusetts. The board has very courteously allowed me to look over and collate the replies which have been received, and I am therefore enabled to give you more extended results than would otherwise have been possible, in anticipation of the Board's Annual Report.

The Secretary, Dr. Abbott, will work over these same returns for the Board's report; but it is not amiss that returns as complicated and as difficult of interpretation as these are should be handled independently by more than one individual, that possible errors or prejudices may be modified, on one side or on the other.

The following is a copy of the circular. Those sent to physicians and public institutions were the same; those sent to factories and employers varied as indicated in questions numbered 1, 3, 4, 5 and 6. The question in regard to sex is somewhat ambiguous.

COMMONWEALTH OF MASSACHUSETTS.

OFFICE OF STATE BOARD OF HEALTH,
13 Beacon St., Boston, January, 1890.

DEAR SIR: In view of the general epidemic of influenza now prevailing, the State Board of Health desires to obtain such information as is possible regarding its appearance in Massachusetts during the present season, and, therefore, respectfully requests a reply to the following questions:

- (1) What was the date of first appearance of the epidemic in your neighborhood? (or institution?) (or among your operatives?)
- (2) In what week was it most prevalent?
- (3) What estimated proportion or percentage of the population in your community was attacked? (or of persons employed by you?)
- (4) What ages or periods of life were most affected?
- (5) Which sex was affected most severely?
- (6) What was the average duration of the attack (or length of absence from work?) in days?
- (7) What symptoms predominated in the cases under your observation?

* In the Mercantile Circular, Nos. 4, 7 and 8 were omitted.

- (8) What other diseases were increased in frequency or severity simultaneously with the epidemic of influenza?

MANUFACTURER'S CIRCULAR.

- (4) What proportion or percentage were obliged to leave their work in consequence of such illness?
- (5) What was the average duration of the attack?
- (6) Which sex was affected most severely?

Respectfully yours,

SAMUEL W. ABBOTT, *Secretary.*

From physicians, 192 replies were received; from public institutions, 24; from factories and employers, 178 replies were received.

PUBLIC INSTITUTIONS — SUFFOLK COUNTY.

The returns from nine of the principal hospitals of Boston, including the Marine Hospital at Chelsea, and the Boston Lunatic Hospital at South Boston, cover about 2,000 people, and indicate that the epidemic began in these institutions about December 21st, and was most active during the week from December 28th to January 4th. The City Hospital reports the earliest first case occurring December 16th, the New England Hospital the latest first case occurring December 23. The McLean Asylum, Somerville, reports the smallest percentage of inmates affected, namely: 10%. With 336 inmates there were 34 cases, of whom 16 were male and 18 were female; only two patients were attacked, the other 32 cases being among the attendants or employees. The New England Hospital for Women reports the largest percentage (75%) of inmates affected. At the Children's Hospital 75% of officers and employees were attacked, and only 33% of the patients; adults reported as somewhat more susceptible than children. At the Adams Nervous Asylum 45% of the inmates — 30 out of 65 — were attacked; at the City Hospital 25% of the patients and 25% of officers and employees. At the Massachusetts Hospital, Dr. Pratt writes: "it seemed at one time that every one resident in the hospital had symptoms of the disease," and nurses and attendants were especially victims. At the State Prison, Charlestown, 40% of the inmates were attacked, the first December 21st; and Dr. Sawin writes, "there was not a single case of pneumonia at the prison, although I saw many cases in private practice"; on the other hand, 8% of those affected had diarrhoea, and bronchitis was as usual frequent.

Conclusions. — As to dates these returns agree pretty well with those of the mercantile companies, and those of the doctors, with the natural difference that these first cases are reported, as a rule, a few days later. Of seven reporting the percentage of patients attacked, the average is 41%. I do not feel justified in drawing any positive conclusion as to sex. There is nothing which appears positively to indicate exposure to the atmosphere or contagion as a factor, unless in the case of the McLean Asylum, where only two patients were attacked, and of the Massachusetts Hospital where the attendants suffered more, one infers that the attendants were more out of doors. At the City Hospital, on the other hand, the percentage of the two classes was equal; and in regard to the Children's Hospital, where 75% of officers and employees suffered but only 33% of patients, it is to be remembered that children were in general less susceptible to influenza.

Of these institutions, the City and Massachusetts

Hospitals are the only ones reporting pneumonia as a complication of or sequel to influenza.

PUBLIC INSTITUTIONS—OUTSIDE OF SUFFOLK COUNTY.

Outside of Suffolk County, 12 public institutions reported, of which five are Insane Hospitals, one (at Tewksbury) an almshouse, and the others are schools or reformatories. Danvers is the most easterly and Northampton the most westerly point represented, and, strangely enough, each reports its first case as occurring on the same day, December 25th, and, contrary to what might be expected, the epidemic reached its height at Danvers Lunatic Hospital as late as the third week of January, whereas at the similar Northampton institution it culminated the second week of January; at Danvers 30% were attacked, but at Northampton only 10%.

The Tewksbury Almshouse (North Middlesex) with its constant receipt of inmates from Boston, reports the earliest first case, December 18th, only two days later than the first case of the Boston City Hospital; the Primary School at Monson (East Hampden) and the Lyman School for boys at Westboro' (West Worcester) come next with December 19th, although the Homeopathic Insane Hospital at Westboro' and the Massachusetts Reformatory at Monson do not report their first cases until December 22d and December 26th respectively.

The latest first cases occurred at the Lancaster State Industrial School (Worcester) and the Worcester Insane Hospital, at each January 3d, but the most active week at the former was the third week of January, and at the latter the second week. The Taunton Insane Hospital (Bristol), reports its first case December 30th; the State Farm, Bridgewater (Plymouth), December 31st; but the culminating week at the former was the third week of January, and at the latter the second week.

The epidemic reached its height a week earlier at the Primary School at Monson than at the Lyman School, Westboro', last week of December and first week of January respectively, although it first appeared at both on the same day. The largest percentage attacked was at the Primary School, Monson (56%); the smallest percentage (5%) at the Worcester, and the next smallest (10%) at the Northampton Insane Hospital. The Lyman School for boys reports 50%; the Lancaster Industrial School 42%; the Reformatory Prison for Women, Sherborne, 40%; the Tewksbury Almshouse 40% of its officers, and 33% of its inmates.

The Danvers Hospital, with 30% of inmates attacked, reports an intercurrent epidemic of measles with nine cases, and one of erysipelas with six cases; there were a few committals in which the exciting cause seemed to be influenza; the senile were less frequently affected by influenza and females more than males. At the Westboro' Hospital "more females were attacked, but the worst cases were males"; at the Worcester Insane Hospital more males were attacked. The Woman's Prison, Sherborne, is the only institution specifying insomnia as a complication. Only four of this group report pneumonia as a complication or sequel.

Conclusions:—In the reports of these twelve institutions it certainly does not appear that geographical position was an important factor as influencing the

date of the first case or the maximum week. How far contagion could have had an influence we have no data to decide; all these institutions are on more or less frequented lines of travel and all receive inmates from the outside world.

The letter⁴ accompanying the report of the Lyman School for Boys, Westboro', taken alone, suggests contagion. No very definite conclusions can be drawn as to the matter of sex.

The average per cent. of the affected at eleven institutions reporting was 32%, compared with an average of 41% in Suffolk County.

MERCANTILE AND MEDICAL RETURNS.

Returns were received from 178 manufacturers and mercantile houses, representing all the counties of the State except Dukes and Nantucket. Of these I have tabulated 142, leaving out those which for one reason or another seemed too vague or unreliable. It cannot be said that all those, by any means, which have been included are entirely trustworthy, some are evidently more careful than others, but on the whole, perhaps, the errors to some degree tend to correct each other. I have endeavored to compare these returns from manufacturers with each other and with those from the doctors throughout the State, of which 192 were received and of which I have tabulated 179. I fear the success as to results is not proportionate to the amount of labor involved, but such as it is I will ask your attention to it.

Beginning with south-eastern and eastern counties, I will pass to the western counties in order.

NANTUCKET COUNTY.

This Island County, standing with its neighbor Dukes alone as outposts in the Atlantic, sends only medical returns, for the good reason that manufactures do not exist. There are five medical returns from the town of Nantucket and vicinity. One places the first case December 20th, and the maximum week the first week of January; the other four range the first case between December 30th and January 4th, three make the third week of January the maximum week and one the second week.

Three think males were more affected, and two females. One reports pneumonia as increased, and two pulmonary diseases. The only return as to proportion of population affected, states 25%.

DUKES COUNTY.

From this Island County also there are only medical returns; here, as at Nantucket, the population lives mainly by the sea.

There are five returns. The earliest first case is reported from Vineyard Haven on the north shore December 25th, but this was one of several exotic cases brought in by the Revenue Cutter *Gallatin*, and another return from the same place dates the first native case January 2d; the other three returns from Edgartown, Cottage City, and West Tisbury date the first case January 1st; three returns giving a maximum week, name first, second and third weeks

⁴ "The first case was a teacher in one of the Schools who had charge of thirty boys. About December 14th she spent a day in Boston, and was taken ill December 19th, recovering in four days. In about five days the boys in her school began to sicken, and it is believed they had the disease before the teacher did. I should say all were within a week and before the disease appeared in any other school. The disease then invaded the nearest school, and in a few days had reached all of the six which make up the institution. Out of 190 boys, 132 had the influenza."

of January; these same returns give 20%, 33% and 66% as the proportions of population affected. Average 40%. Two returns state that males were more affected, and one that females, "because males had greater power to throw off the disease quickly." One return gives pneumonia and one pulmonary diseases as increased.

Conclusions. — The return from these island counties indicate that influenza invaded them two weeks later than the mainland further east. In the winter months they have comparatively little communication with the mainland; the population is thus less exposed to contagion, though freely open to atmospheric effects, especially those coming from the eastward across the Atlantic.

Before drawing the obvious conclusions in favor of contagion and against atmospheric miasm I ask your attention to two interesting letters.

Dr. Banks, Surgeon Marine-Hospital Service, writes from Vineyard Haven, January 25th: "December 25th I treated seven cases, seamen landed from the Revenue Cutter Gallatin which put in here in consequence of this trouble with her crew." This is the first record I have of the appearance of the epidemic here, and shortly after I was seized with an illness of a like character. . . .

"In this connection as showing an undoubted atmospheric influence in the propagation of the disease, read a report similar to mine comprising seventeen cases on the Revenue Cutters* Woodbury and Dallas at Portland, Me., which occurred on board these vessels while at sea attending to their duties in cruising along the coast."

Dr. Luce writes from West Tisbury, January 31st:—"I first observed the epidemic during the spring of 1889, when it appeared in its greatest severity during the months of March and April. It was not then epidemic in the State, so far as I know. I should think that at this time about one-third of the inhabitants were affected. . . . It was most frequent among males, especially among fishermen and those exposed to inclement weather. The symptoms in this epidemic were principally referable to the respiratory organs.

"The present epidemic began about the first of January and is still upon us, affecting fully two-thirds of the population. In some instances the schools have been closed, so many of the pupils were affected. It affects all ages, but is principally confined to males.

"The symptoms are more variable than in previous epidemics. I think I recognize three different forms of the disease: (1) bronchial or catarrhal; (2) febrile, with a second rise in temperature after the drop in several cases; (3) neuralgic.

"I have seen only one case of supervening pneumonia, and that was in the spring epidemic. I have seen in connection with the present epidemic four cases of herpes zoster, more than I have seen here before in many years. Influenza seems to be a common disease here."

Dr. Lane writes also from Vineyard Haven: "There was no evidence of its being communicated by or from one person to another, even when occupying the same room or bed through severe cases lasting two weeks."

* Abstract of Sanitary Reports, January 3d.

* Ibid., January 17th.

BARNSTABLE COUNTY.

This county furnishes only one manufacturer's return, and that from a shoe shop at Orleans on the arm of Cape Cod. The first case occurred January 14th, the greatest prevalence was during the fourth week of January, 33% of sixty-six employees were attacked and absent from work on an average of four days. The return of the doctor at Orleans, on the other hand, reports the first case as occurring in his neighborhood on December 27th, the greatest prevalence during the first week of January, 33% of the population as affected, males the most severely affected, and pneumonia as increased.

Medical Returns. — From physicians in Barnstable County there are fifteen medical returns from eleven towns, all the way between Truro on the northeast arm of the Cape to Sandwich at the southwest border. At Truro the first case is dated January 1st, and the greatest prevalence the last week of January; from Wellfleet, ten miles away, the first case is reported November 20th, and the prevalence the third week of January; Chatham, December 22d and the second week of January; Harwich, January 1st and second week of January; Brewster about the same; West Dennis, December 20th and second week of January; but South Dennis, December 1st and first week of December. Of two reports from Hyannis, one places the first case December 10th, the other December 25th. Of four returns from Sandwich, one places the first case October 6th, two December 20th and one December 27th; one gives the first week of January as that of greatest prevalence, two the second week and one the third week; one reports 50% of the population of Sandwich as mildly affected and 12% severely, another 30%, and another 25%.

Conclusions. — The greatest percentage of affected (75%) is reported from Harwich, West Dennis and Osterville; the least percentage (10%) from South Dennis; of the two reports from Hyannis one gives 10% as affected, and the other 25%. The average of thirteen towns is 37%.

Sex. — The only point which can be fairly well established from the Barnstable medical returns is, that males were more severely affected than females, and probably — as one doctor puts it — "because they were more exposed to the weather." Ten out of fifteen report "males," two females, one is doubtful, one says no difference. From Sandwich one return says "males," one says "females," one "rather more females," and one says "no difference." So that, on this point, Sandwich remains in doubt.

Other Diseases. — Six returns from this county report pneumonia as increased, and four pulmonary diseases.

(To be continued.)

— The House Committee on Invalid Pensions has agreed to report favorably a bill which provides that all women employed by the Surgical Department of the United States as army nurses or otherwise officially recognized as such during the late war, and who served in hospitals, in camp or on the battlefield for six months or more, and who were honorably discharged, and who, from the results of such service or the infirmities of advancing age, are unable to earn their own livelihood, shall receive a pension of \$12 per month.

CASES ILLUSTRATIVE OF SOME OF THE MORE UNUSUAL FORMS OF BLADDER DISEASE AMONG WOMEN.¹

BY CHARLES T. STRONG, M.D.,

Physician to Out-Patients, Massachusetts General Hospital; Assistant Surgeon, Free Hospital for Women; Assistant in Gynecology, Harvard Medical School.

THE cases to which I invite your attention by the clinical notes I shall give this evening I have selected as representing either by the unusual severity of their symptoms or the obscurity of their lesions, some of the less common types of vesical disturbances. We are familiar with the more common forms which occur as accompaniments of gynecological conditions, either as reflex or mechanical processes; of those which disappear with but little if any local treatment, I shall not speak. The tendency is to assume that, given any pathological condition of the reproductive organs, bladder symptoms must by this be accounted for. Hence too often, exploration and careful diagnosis are neglected or postponed, and a disease which might be mild in its beginning becomes an intractable, chronic affair. Nothing is simpler than an examination from the meatus to the exploration of the whole interior of the female bladder. The endoscope with electric light is valuable but not necessary. The small endoscope I show here is sufficient, with the aid of an ordinary head-mirror and lamp. Since the introduction of cocaine, ether is not necessary, but is always preferable. Simon's plugs are the most desirable form of dilators and furnish, too, an efficient instrument of aid in medicament.

The first cases I shall consider are those of hemorrhage from the bladder, not from malignant growths but from the villous formation resulting from chronic cystitis. These are not the usual forms in which the disease manifests itself. I have met with four cases in which a diagnosis of malignant disease of the bladder had been made, but which were cured without return, by the treatment employed.

The most pronounced cases were the following:

Mrs. McL., thirty-eight; married; no children. Hemorrhage from the villi of chronic hyperplasia of vesical mucous membrane. Referred to me in 1881 for palliative treatment of malignant disease of the bladder. In four years there had been steadily increasing pain about the bladder, with but little pain in micturition. The urine at times appeared slightly bloody. During the past year there had been decided deposits of a blood-stained sediment, and in the past eight months decided hemorrhages had occurred, with the passage of large clots. During the past two months hemorrhage had been so excessive as frequently to induce syncope. The patient was blanched, and certainly looked as if she had the cachexia of malignant disease. Micturition was frequent, but not extremely painful. The passage of a sound started up such decided hemorrhage that it was necessary to dilate rapidly the urethra, which was free from disease. The finger entering the bladder met everywhere soft villous formations, many of which were capped by a phosphatic deposit. These outgrowths were especially massed in the vicinity of the ureters. The sharp curette was used to remove these, leaving a clean base everywhere, and immediately stopping the hem-

orrhage. The bladder was drained and irrigated several times daily with boracic-acid solution. The convalescence was uninterrupted, and the patient still continues well.

The treatment employed here is that with which I have obtained the best results in this class of cases; and in chronic cystitis it may well be employed. The curette is quite as useful in hyperplasia inside the bladder as within the uterus, and if employed early would in not a few cases do away with the necessity of establishing permanent fistulae for drainage.

The cases in which frequent micturition is continued by a contracted bladder after cure of the original vesical disease form a series of which I wish to speak. Normally containing with ease a much larger quantity of urine than the male bladder, in consequence of lesions which especially involved the urethra, the bladder, by its reflex activity, is continually contracting, acquiring thickening of its muscular walls and assuming the shape of a firm, round ball with a very small cavity. There is but one treatment for this,—steady and progressive dilatation by frequent hyperdistension with aseptic solutions. Systematically pursued, this will certainly effect a cure, although much time may be required. An illustrative case is the following:

Mrs T., single, twenty-two, consulted me October 26, 1883. For five years she had suffered from too frequent micturition. The exciting cause, she thinks, was hyperdistension from voluntary retention. From a comparatively insignificant beginning her condition had steadily grown worse, and at this time she passed her water every twenty minutes or oftener, day and night. For two years past she had received constant local treatment, but had never been examined. She was, of course, debarred from every enjoyment, and reduced nearly to a condition of insanity from the loss of sleep and the suffering accompanying each act of micturition. The largest quantity of urine she had voided at one time for many months was less than four drachms, and this was in consequence of the rest obtained by opiates.

There was an anteflexion of the uterus, but without either it was impossible to make a vesical examination, and as the patient refused this, for a month, I made a thorough trial of diluents and internal medication, and such sedatives as were not opiates. Her condition steadily grew worse. I had her keep a record of the number of times she attempted to pass water during twenty-four hours; the intervals averaged ten minutes.

Early in December, under ether, I made a thorough examination with the endoscope. The bladder wall was clear and free from inflammation, as I had been led to expect by the character of the urine. The urethra was the seat of intense chronic inflammation. I applied over the whole surface a strong solution of nitrate of silver. For the next few days the bladder was in a state of constant tenesmus, requiring full opiates to control it; but as soon as the acute reaction from the treatment passed away, almost imperceptibly the intervals between the acts lengthened.

January 15th. She retained her urine one hour.

February 15th. For several days has retained urine two hours during the day and two and one-half at night.

Early in March she had an attack of catarrhal gastritis which greatly reduced her, and there was a re-

¹ Read before the Obstetrical Society of Boston, April 12, 1880.

lapse to intervals of thirty minutes to one hour. Just previously to this attack she had gone three hours, twice, the longest period for years; but the quantity she passed at this time was not much increased. Up to this time I had been satisfied to refrain from any interference with the urethra except by weekly or bi-weekly injection of a very weak solution of nitrate of silver. Examining again, I found there were several patches of urethritis that were not healed, and upon these the strong solution was applied; and again the interval lengthened to two hours.

There was one feature now prominent in the case that puzzled me. On one day she would pass her water every two hours; perhaps the next day she would go three hours or longer; and again the variation might be as great during different parts of the same day. Eliminating other causes, I attributed this to the amount of urine which was contained in the bladder, varying at different times, and found that when a certain limit was reached the call was imperative. I demonstrated with the syringe that when the amount of fluid in the cavity was more than three ounces then the desire to empty it was pronounced, and four ounces produced intolerable pain. As the patient was now quite strong, I began systematic dilatation by hyperdistension, and also instructed her to retain the water just as long as possible. Following out this course produced the most gratifying results. The progress was slow but steady.

In July she could with very little discomfort, retain the urine an hour after she first felt the desire, and after having been one year under treatment, she could attend to all her duties, social and domestic, free from any disturbance from her bladder. She usually rose once during the night, but not always; and during the day the intervals were no more frequent than normal. There has been no relapse.

The treatment of this case is that which I have found most uniformly successful in inflammatory lesions of the urethra. It is the application of a strong, almost caustic, solution of nitrate of silver through the speculum directly upon the seat of the disease.

CASE III. Retention of urine as a neurotic manifestation, with cystitis and subsequent malignant disease of the vulva, surrounding and including meatus.

Mrs. C., age thirty-seven, May 11, 1887, was referred to me, with the history that three weeks previously (April 18th) there was stoppage of urine, accompanied by bearing-down pains. This had never before occurred. The urine was drawn, but stoppage occurred again the next day. In short, the catheter had been required seven or eight times during the three weeks. Upon all other occasions the act had been perfectly normal. The closest questioning failed in eliciting any reason why the urine should pass at one time and stop at another. There was never any pain. The time of day or night, the condition, exercise or rest, none of these were disturbing factors. Once started, the stream always continued until the bladder was empty; but unless it started freely and immediately, neither straining or any of the usual aids, such as using water, etc., were of any avail. The only symptom the patient felt was "a kind of clicking feeling," and then the stream would not come. There was no uterine lesion.

It was difficult not to attribute the condition to some material obstruction as the patient was apparently as free from nerves as any woman one could meet,—a

large, strong woman in the best of physical health. Since her catheterization the urine, she noticed, had become cloudy, and I found it full of pus. Evidently she now had cystitis, but improved decidedly with proper treatment. I could find no local lesion whatever by most careful endoscopic examination. There was no retention and no treatment for the next five weeks. Then, in consequence of living some days in the midst of fresh paint, as she thought, she had stranguary and retention. Again a month's freedom and one day's retention. Without ether I dilated until I could easily pass my finger into the bladder, which I explored thoroughly with curette, forceps and finger, but with former results. Following this, there was an interval of four months of freedom; then the catheter was once required; then two months' rest again. This brought the time to January, 1888. In examining, now for the first time, I thought there was some spasm at the neck of the bladder, so, January 18th, under ether, a most thorough dilatation was made, and the bladder and urethra explored in every way, but with entirely negative results. However, the patient was greatly relieved, and nothing more was heard of stoppage until January 18, 1889, just one year to a day from the last decided operation; then occurred retention. So matters went along through the summer. Occasionally, following a day of overfatigue or some severe mental strain, the urine would have to be drawn. There was no regularity.

The patient occasionally wrote to me; but having made up my mind that the trouble arose from some neurotic condition and would continue as long as the cause, I refused to do anything more; but in November, she appeared, stating that for a week past she had not been able to pass any urine, except it were drawn. Although the condition of the urethra and bladder still seemed normal, I noticed on each side of the meatus, and extending in a less marked degree above and below it, a hyperplasia of the vulva tissue, which seemed quite indurated at the base. This increased rapidly, and was extending up the under surface of the urethra into the vagina. A piece submitted to Dr. Whitney was reported upon as follows:

BOSTON, January 2, 1890.

DEAR DOCTOR:—I have examined the specimen from the meatus received from you from the Free Hospital. It is composed of a connective tissue base, covered by thickened and irregular masses of epithelial cells. In general, the growth has the aspect of a papilloma, but in one place the cells have a tendency to dip into the tissues of the base. I am suspicious that it will recur.

Yours truly, W. F. WHITNEY.

I operated upon this thoroughly, removing all the diseased tissue. During convalescence retention occurred once, but ceased as soon as the dressing of iodoform was omitted.

I last saw the patient about a fortnight ago, and she reports that, at irregular intervals, the catheter has been necessary. I have given her a full-sized No. 30 bougie to use with regularity, hoping in time to overcome the trouble with the sphincter.

The nature of the case in one way is plain to me, that is, that many of the occasions when resort to the catheter has been necessary, are hysterical in their origin. But why the first retention in a woman whose mind, so far as can be told, has never been directed towards her bladder? There has been no attempt to win sympathy. The more I treat her the more last-

ing the relief; and yet neither I nor the gentlemen who have seen her with me have been able to find, either in the urethra, bladder or reproductive organs, any condition that would suggest a mechanical or reflex cause.

The occurrence of the malignant disease I regard as a coincidence merely. It is in this situation, an extremely serious condition, I have seen two, possibly three, similarly situated; and these have been more ulcerative in their character than this. Although I cut and burned thoroughly, yet I cannot but feel there is the strongest liability to return of the disease.

I have regarded the development of malignant disease as a coincidence merely, but I am reminded by it of the development of a similar condition about an artificial vesico-vaginal fistula in a patient whom I had the opportunity of seeing with Dr. Forster. This raises the question in my mind as to how far the repeated dilatation might have been responsible for it.

CASE IV. The tendency to the formation of villous growths in chronic cystitis is rare, but even less common is it to meet with this condition in the urethra. I have seen it in but a single case, and in this associated with distinct fissure at the neck of the bladder and caruncle at the meatus. The cause of the trouble here was evidently mechanical, the cervix of a retroverted and immovable uterus being crowded hard against the urethra.

Mrs. W., age thirty-nine, consulted me first in June, 1887, for relief from constantly increasing frequency of micturition, accompanied by pain, tenesmus and bloody urine. The pain was of cutting character, and extended up both sides of the pelvis to the back. When it was possible to pass the water in a standing position the pain was diminished. Under no circumstances could the urine be retained if the inclination to pass it had been felt, and two hours was the maximum interval between the acts for several months past. The symptoms dated back about two years, but then the onset had been gradual. The urine was quite clear, except for the presence of some free blood. The patient had been told that all her troubles were due to the caruncle; but as this had been removed several times without relief, there was evidently some further lesion.

Under ether, by the endoscope the urethra was seen to be covered with varicose and dilated blood-vessels in villous outgrowths from the meatus to its junction near the bladder. They stopped abruptly here, but there was a deep fissure at the vesical neck upon the lower side. The urethra was thoroughly dilated, its surface scoured and scraped, and painted with a strong solution of argentic nitrate. The walls of the bladder were hypertrophied, and the cavity would contain about three ounces. This treatment was followed by the bi-weekly injection of a weak solution of nitrate of silver and suppositories; but the latter, as in most of the cases that I have seen, appeared rather to increase the patient's discomfort, and their use was abandoned.

At the same time, I attempted replacement of the uterus, but this was too irritating, and except the employment of a single glycerine tampon placed so as to relieve the urethra as much as possible from pressure of the cervix, was abandoned. The patient steadily gained, except in the frequency of micturition which I attributed to the same cause largely as in Case II, namely, a contracted bladder. Systematically dilating it by hyperdistension, I had the satisfaction of over-

coming this condition, and in September the patient was so well that she ceased attendance against advice, as I felt sure the cervix would again set up trouble.

In January, 1888, the danger-signal of the cutting pain on micturition forced the patient to come again for treatment. I found two patches, each about the size of a split pea, midway of the urethra, showing the characteristics of a subacute urethritis. With cocaine as an anesthetic these were quickly dissipated; and at the same time, by packing with great care, I was able to lift the uterus enough to free it from the pressure of the cervix. Since that date the patient has been perfectly well except for the slight local irritation of the caruncle, which has recurred twice. Should it again appear, I shall make a thorough dissection to remove entirely its base.

It was interesting here to follow the gradual and steady improvement that accompanied the treatment. Few, if any, classes of cases are more exhausting to the nervous strength of the patients than these of vesical disturbance, and the reaction of the local and nervous conditions upon each other are most unhealthy.

This case is one in which drainage through a vesico-vaginal or urethro-vaginal fistula would have been resorted to, I think, by many operators; but as it was possible to give the patient all the necessary attention, it seemed to me the more conservative course was the better. Despite all that may be said in their favor, fistulae put patients in uncomfortable relations to themselves and their surroundings; and one should, I feel, hesitate, and try many conservative lines of treatment before subjecting a patient to their annoyances and discomforts.

THE INFLUENZA EPIDEMIC AS OBSERVED AT THE BOSTON LYING-IN HOSPITAL.¹

BY CHARLES M. GREEN, M.D.

THE cases of influenza observed at the Boston Lying-in Hospital during the late epidemic were neither numerous nor severe. But no unusual complication of the puerperal state is devoid of interest, and it has therefore seemed worth while to examine the clinical history of these cases with a view to the lessons which they may teach.

The first seizure of the epidemic was observed December 24, 1889; the last, January 22, 1890. During this period of about a month there were fifty-two women in the hospital, and among this number there were seven cases of *la grippe*, or 13.4%, — a small proportion probably compared with that obtaining in the community at large.

CASE I. Normal primiparous labor, December 20, 1889. Convalescence normal until the morning of the fourth day, when the temperature was 99° F., and the patient did not feel well. Evening temperature 102°, pulse 90; complaint of pains all over, with fulness of the head and some coryza, but no sore throat and no cough. Lochia abundant and sweet; no tenderness over the uterus. Early next morning patient had a chill, and temperature rose to 102.4°, but later dropped to 100.4°; evening temperature 101°, pulse 106. After the chill patient was given quinine sulph. gr. x; but she received no other treatment except occasional mild aperients or enemas. The temperature fell gradually, was normal on the

¹ Read before the Obstetrical Society of Boston, April 12, 1890.

morning of the ninth day, and the patient left the hospital well five days later.

CASE II. Normal multiparous labor, December 26, 1889. Convalescence normal until the evening of the fifth day, when the patient had a well-marked chill, the temperature rising from 99° to 102.4° , and the pulse from 70 to 112: the right breast was somewhat tense and painful and there was some cough. Next morning the temperature was 99° , pulse 72; but in the forenoon there was another chill with pulse and temperature 84 and 100.4° respectively. There were no symptoms pointing to any trouble about the uterus, nor was the tense breast considered sufficient to account for the chills. That evening the pulse was 116, and the temperature rose to 104° : ten grains of antipyrine were then given, and the next morning the pulse had fallen to 88 and the temperature to 99.8° : the next day pulse and temperature were normal, and there was no further disturbance. On the twelfth day, however, when the mother was convalescent, the baby was seized with coryza, conjunctivitis and bronchitis and presented a perfect picture of the catarrhal form of the epidemic. This was the only case observed among the infants in the hospital.

CASE III. Normal primiparous labor, December 27, 1889. The first stage was tedious, and the patient was rather exhausted, as may be inferred from the pulse and temperature, which did not fall to normal till the morning of the third day from the beginning of labor. On the morning of the fifth day of the convalescence the temperature was 99° ; in the evening it was 101.4° , and there was complaint of headache and backache: lochia normal. In three days these symptoms had disappeared and the temperature was normal.

CASE IV. A normal primiparous labor, December 22, 1889, and an uneventful convalescence, except from toothache, until the fourteenth day, when the morning temperature was 102.8° and pulse 100. Later in the morning, there was a chill and the temperature rose to 104° , the patient complaining of pains in the head and back. She was given ten grains of antipyrine, kept in bed, and in two days pulse and temperature were normal.

CASE V. Normal primiparous labor and normal convalescence until the sixth day when the patient did not feel well, although the temperature and pulse were normal. Two days later the breasts were cakey and were rubbed with camphorated oil. Next evening the patient had a chill and the temperature rose to 103.4° ; there was headache. Next morning the temperature was normal and there was no further disturbance. This may not have been a case of gripe, but it had that appearance; and it did not seem that the subsiding tension of the breasts could have caused the symptoms.

CASE VI. Easy primiparous labor, January 9, 1890. On the fourth day there was some headache; temperature normal; but on the sixth day the temperature rose to 103° in the afternoon, after quite a severe chill. There was some pain in the thighs, but no catarrhal symptoms and no evidence of sepsis. On the following day the morning and evening temperatures were 99.5° and 102° . A macular eruption with an occasional pustule appeared on the left breast. Next morning the eruption was more extensive, invading the axilla and passing around on the back. Morning and evening temperatures 100.8° and 100.4° .

Next day the temperature was normal, and two days later the eruption was disappearing.

CASE VII. Rapid, easy primiparous labor, January 10, 1890. Convalescence normal until the evening of the fifth day when the temperature rose to 100.6° , with no other symptoms. Next morning a slight macular eruption with an occasional pustule appeared on the right breast, the appearances being similar to those reported in Case VI. In two days the temperature was normal. In this case the elevation of temperature was not marked and the constitutional disturbance not very marked; but the eruption and rise of temperature resembled that observed in Case VI who occupied the next bed but one in the same ward, and the case was thought to be a mild seizure of *la grippe*.

Of these seven cases it may be said that the symptoms were mild for the most part: in five cases there were one or more chills and decided elevation of pulse and temperature. In two cases there was a macular and pustular eruption: in general the symptoms were headache and backache, malaise with coryza and cough; but the catarrhal symptoms were mild, except in the case of the baby previously reported. In no case was either nausea, vomiting or diarrhoea observed.

No patient entered the hospital while suffering with influenza, so that no opportunity occurred to observe what effect, if any, the disease might have on the progress of labor. Neither was there any instance of premature labor induced by the epidemic influenza. There were several cases, however, who entered while convalescent from the gripe, whose labor and puerperium gave evidence of preceding prostration.

The most serious feature of the epidemic, from the physician's point of view, was the apprehension occasioned by chills and sudden elevations of temperature. In puerperal convalescence such phenomena cannot fail to excite alarm until the diagnosis is clear as to whether the cause is a transient and unimportant one, or whether it is to be attributed to septic absorption. In each case, therefore, great care was exercised to accurately explain the changes in temperature before reaching a diagnosis.

Such being the history of the epidemic among the patients, let us briefly examine the experience of the other members of the household. The regular complement of attendants embraces six day, and three night, nurses; but during the epidemic there was one vacancy among the nurses, and numerous substitutes were employed as occasion required. Of the eight regular nurses four succumbed to the epidemic; and one night nurse was sick enough to have done so, but pluckily attended to her duties. Accurate histories were not kept of the nurses' sicknesses; but they were all sicker than any of the patients, with perhaps one exception. One nurse had an evening temperature of 105° , was delirious during the night, and required the attendance of a special nurse: there was backache and great prostration; but the temperature gradually dropped and she was on duty in two days. Another nurse suffered with cough, tonsillitis and prostration for three or four days, with a temperature of 101° and 102° . Another had an evening temperature of 103° , and was so prostrated by the attack that, although out of bed in two days, she was obliged to rest for a week before returning to duty.

The Matron and the Director of Nurses also suc-

cumbered to the epidemic and were unfit for duty for two or three days. Two serving women were also seized, suffering like the others with high temperature, pains in the back and head and great general prostration.

It is interesting to notice the contrast between nurses and patients suffering with the epidemic, in respect to the severity of their symptoms,—the latter suffering much less severely than the former. This was obviously due to the fact that while the nurse was actively at work and frequently overworked, the patient was quiet in bed, in favorable surroundings, and on a more or less restricted diet. It is reasonable to suppose that had the patients been in their own less hygienic homes, subjected to the mental annoyances and disturbances of family life in average tenement-houses, and without trained nursing they would have suffered much more severely. Indeed, one of the out-patients, who had a long, difficult labor, terminated with forceps, was seized with *la grippe* on the sixth day and was very much sicker than any patient in the hospital. Her evening temperature was 104°, pulse 112, there was coryza, and severe general pains, even in the fingers. The evening temperature next day was 104.8°, and the following morning it had risen to 105.2; but from this point the fever declined and the patient made a gradual, but slow, recovery.

CASES OF CYSTITIS TREATED WITH SALOL.¹

BY S. L. ABBOT, M.D.

CASE I. On entering on my service at the Massachusetts General Hospital, March 1, 1888, I found in my female ward a patient who had been admitted on the 12th of February, suffering with severe uterine symptoms and pelvic cellulitis. On the 13th her urine had been drawn by a catheter for examination and was found to be normal in appearance, acid, of specific gravity 1.020, containing no albumen, depositing a slight sediment.

The patient's general condition was bad. She was much emaciated, had severe night sweats, and the pelvic symptoms were severe with high temperature up to the 22d, when there was some mitigation of them, but micturition was frequent and painful. At this time the urine was pale, alkaline, of specific gravity, 1.014, and contained a small trace of albumen, a little blood and much sediment of pus and mucus, with triple phosphates.

March 1st. Urine strongly ammoniacal, alkaline, otherwise about as on February 22d.

Palliative remedies had given considerable relief, such as washing out the bladder with borax water, and rectal suppositories of morphia,—and acid, nitro-muriatic m. xv had been given three times daily. On this day these remedies were omitted with the exception of washing out the bladder. Five grains of chlorate of potash were prescribed to be taken every two hours.

March 2d. After the administration of eight doses of the chlorate, the urine was of normal color and odor, acid, of specific gravity, 1.018. It contained a slight trace of albumen, and there was some sediment consisting of a small amount of mucus and pus, a little normal blood, and fine and coarse granular and hyaline casts. The patient complained of pain in the lower

left front chest, and some dry friction sounds were heard at this spot. The chlorate of potash was omitted.

March 4th. The urine was again alkaline and in other respects as before the use of the chlorate. This, with the bladder washing, was resumed, as the chest symptoms had subsided, and an iron tonic was also prescribed.

There was a gradual increase of strength and on the 12th the record shows that the patient sat up five or six hours.

On the 16th, the urine was reported as unchanged, the purulent deposit being one-third of the whole bulk.

March 17th. The patient had been up all the day before and was now complaining of moderate rheumatic pain in the left shoulder and right side. Examination of the chest gave a negative result. All the remedies were omitted, and salol gr. x was directed to be given three times daily.

March 18th. Rheumatic pain relieved, and the urine has undergone a great change being acid for the first time in two weeks, pale, of specific gravity, 1.018; containing a small trace of albumen and a greatly reduced sediment. The treatment was continued until the 24th when the urine was still acid and contained very little sediment. Salol omitted.

March 25th. Urine alkaline again. As the patient's condition now admitted of a more powerful salicylic remedy, salicylic acid gr. v was prescribed, to be taken every three hours.

On the 28th the patient was discharged well. She has been seen frequently since leaving the hospital, by my assistant Dr. Greene, and she continues well.

CASE II. Mrs. —, a young married lady, called on me in the spring of 1888, complaining of symptoms which she regarded as uterine, from which she had been suffering for some days. On inquiry I learned that her most urgent symptom was very frequent micturition ("every five minutes" as she expressed it), a very small quantity of urine being passed at a time, greatly disturbing her sleep at night. The trouble was increasing and she asked for a uterine examination to determine the cause, supposing that there must be some displacement of the womb. I learned that sexual intercourse had occurred but twice during the month since marriage, without special suffering.

On making an examination the sphincter vaginae was found to be spasmodically contracted and very tender to the touch, requiring some force to pass the finger beyond it. This having been accomplished, the uterus was found high up in perfectly normal position and condition, neither was there any vaginal tenderness above the os tunc except on the anterior surface where firm pressure towards the bladder caused much pain. There was and had been no vaginal discharge, and the symptoms were clearly referable to the bladder. She could suggest no possible explanation of them. The urine at this time was strongly acid. Palliatives, such as the introduction of a few drops of four per cent. solution of cocaine within the vagina, alkalies, morphine suppositories in the rectum and hot hip baths gave some relief, the urine being alkaline on the following morning.

On the next day the patient complained of loss of appetite, the tongue was furred, and there had been a chilly turn the day before followed by profuse sweating; she had had intermittent fever in 1884. The urine was acid, specific gravity, 1.012, without appre-

¹ Read before the Obstetrical Society of Boston, April 12, 1890.

ciable albumen, contained abundant crystals of triple phosphate and muco-pus in large amount, constituting from a quarter to a third of the whole volume on standing.

Two grains of sulphate of quinine were prescribed to be taken before each meal, and the other remedies were continued.

On the next day, as there had been no recurrence of chills or sweating and the bladder symptoms were about the same, all remedies employed were omitted except the hip bath, and five grains of salol was prescribed to be taken every three hours.

On the next day the patient reported very great relief, being able to retain the urine one hour at a time and micturition was much less painful. Urine acid, specific gravity, 1.014, still containing considerable muco-pus and bladder epithelium. From this time the symptoms rapidly improved, and the patient reported herself well on the sixth day after commencing the salol treatment.

CASE III. A widow lady past middle life, was taken in the middle of November, after getting chilled by standing some time in the street exposed to a high wind, with a severe attack of catarrh of the bladder. Painful micturition was very frequent by day and night. At first she was treated with alkalies and rectal suppositories of morphia which gave some relief. During the second week salol was prescribed in the dose of five grains to be taken three times daily and the alkali was omitted. On the third day the salol was directed to be taken four times daily, and bicarbonate of soda in addition if needed.

At the end of the week the urine was nearly natural and the micturition was painless, occurring but twice during the night and three or four times only during the day. In ten days after the treatment was commenced the patient was entirely well. Three days before the conclusion of the case, an iron tonic was prescribed, as a slight attack of diarrhea for one day had caused considerable weakness.

This patient was very much impressed with the efficacy of the salol treatment, as a few years before she had had a similar attack much less severe in character, under the care of an intelligent physician, during which she was confined to her bed for six weeks and required the constant attendance of a trained nurse; while in the present instance she was able to lie on a couch during the last few days of her illness, and the care of her family servants was all that she needed.

CASE OF EPITHELIAL CANCER IN A NEGRESS.¹

BY EDWARD JACOB FORSTER, M.D.,
Visiting Physician, Boston City Hospital.

My attention having recently been called to the rarity of carcinoma in negroes, I am lead to report a case which recently came to my service at the City Hospital.

From the hospital records I condense the following history: Mary C., a full-blooded negress, twenty-seven years old, born in Virginia, entered the hospital February 4, 1890, for treatment for "falling of the womb." Family history negative. Had chills and fever when nine years old; "inflammation of bowels," probably attacks of cellulitis, several times.

¹ Read before the Obstetrical Society of Boston, April 12, 1890.

the last three years ago. Menstruation regular, but profuse; complains then only of dull pain in front passage. Has leucorrhœa. One child several years ago. No miscarriages. Denies intercourse for three years. No pain on micturition. Bowels constipated. General health good; is well-developed and nourished; would be called fat.

Examination showed marked cystocele. Uterus in second degree of prolapse. Sound passes four and one-half inches. Bilateral tear of cervix without marked eversion of lips, a spot about the size of a silver quarter of a dollar on the left side of posterior lip encroaching upon the angle of the tear and extending towards the cervical canal from which the mucous membrane is absent; very slightly excavated, and at the sides extending slightly under the mucous membrane. The appearance was unlike any epithelial growth I have ever encountered in this or any locality, and gave one the impression at first view that it might possibly be a syphilitic lesion.

A piece the size of a ten-cent coin was excised, and sent to Dr. H. F. Sears, who returned the following report: "Microscope shows masses and threads of epithelial cells in connective tissue throughout specimen — epidermoid cancer."

On February 19th patient was etherized, and with the assistance of Dr. Haven, I amputated the cervix. First splitting the cervix on both sides of the vaginal junction, a large wedge-shaped piece was removed from each lip, the mucous membrane of the canal was stitched by a single silk suture on either side to the outside of the cervix, and the remaining portions of the lips united by ten silver sutures. An elastic ligature controlled all hemorrhage. The operation lasted one hour and ten minutes. Patient recovered well from ether. Antiseptic washes and pad used p. r. n. Catheter every six hours. . . .

March 2d. Stitches all removed. Parts firmly united. Uterus found in normal position. After recovery from the customary weakness attendant upon a fortnight's stay in bed, the patient was discharged at her own request on the 13th, and advised to visit occasionally the out-patient department. This advice I am told she has followed; and Dr. Green or Dr. Haven can perhaps tell us of her present condition.

While most all writers recognize and dwell upon the extreme frequency with which uterine fibroids are found in negroes, after a careful search, very little can be found written in regard to the frequency with which carcinoma affects them. That little is nearly if not quite all contained in a paper by Dr. Louis McLane Tiffany in Volume V of the "Transactions of the American Surgical Association" (1887), entitled "Comparison between the Surgical Diseases of the White and Colored Races." He says: "Of malignant growths, the ones most common are the sarcomata, and these are usually in relation with the skeleton. . . . Carcinoma is very rare in the negro"; and that during thirty-four months in the out-patient department of a general hospital where 4,930 cases were treated, 34% of which were colored, no case is recorded of epithelioma of the face or lip of a negro. In his own practice, he can only call to mind one instance of epithelioma of the tongue in a negro.

In the discussion which followed the reading of Dr. Tiffany's paper, Dr. E. H. Gregory, of St. Louis, stated that he had never seen cancer of the lower lip

in a negro. Dr. W. T. Briggs, of Nashville, Tenn., said he thought cancerous affections were not so common as in the white race.

If we can judge by the omission to mention the uterus as a seat of carcinoma by these gentlemen who practice where there is a large colored population and the meagreness of the literature of the subject, the situation in the case just reported is certainly exceptional.

Professor Baker, who first called my attention to this subject, I think, said he had not met with a case.

Dr. C. M. Green who examined this case with me, remembers having seen but one other.

Dr. D. W. Cheever told me yesterday that he could not recall having met with a case of uterine cancer in a negress.

Dr. H. H. A. Beach in a note writes me: "In my own operating, I do not recall but two cases of epithelial disease among negroes, one of the lip and one of the labia majora, the former was a male subject."

The rarity of cases like the ones reported is, I trust, sufficiently shown to excuse me for having taken your time by giving the details of one which when occurring in women of our own race, we are unfortunately only too familiar.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING April 12, 1890.

DR. STRONG reported

CASES ILLUSTRATIVE OF SOME OF THE MORE UNUSUAL FORMS OF BLADDER DISEASE AMONG WOMEN.¹

DR. DAVENPORT said that in many mild cases of urethral irritation the passage of a steel sound gave the same satisfactory result as with similar treatment in cases of mild urethritis in the male. He had never seen the villous condition spoken of by Dr. Strong. He mentioned a case where there was a vesical polypus hanging by a delicate pedicle.

DR. ABBOT said that he was prompted by Dr. Strong's report of his cases to speak of several cases of cystitis which he had successfully treated with salol.²

Dr. Abbot also said that he had recently tested the power of salol in a case of severe acute gonorrhœa in a man, in which the dose of five grains was prescribed to be taken every two hours. The treatment was begun at the end of the second week of the attack. At the end of the third day the patient himself reduced the dose to two and a half grains every two hours, on account of the relief he had experienced, and at the end of five days of the use of this remedy the discharge was reduced to a small drop with almost complete relief from the scalding micturition.

Dr. Abbot referred to the rapid elimination of this antiseptic by the kidneys, and mentioned an instance within his personal knowledge, in which a medical friend had taken a dose as an experiment, and detected its presence in his urine by a chemical test fifteen minutes after.

DR. MINOT was reminded by one of Dr. Strong's cases of a patient, thirty-five years old, unmarried, who

was always well till May 24, 1889, when she found she was unable to pass water. At the end of eighteen hours Dr. Minot catheterized her, and then found a large fibroid tumor of the uterus, which did not, however, press on the urethra, and he was puzzled to account for the retention. The patient had remained well till yesterday, when it was again necessary to draw off the urine. The tumor had increased considerably, but still formed no obstacle to the introduction of the catheter. He supposed that the retention was a reflex phenomenon, but had never before met with such a symptom in cases of uterine fibroids.

DR. RICHARDSON said that he had seen one similar case in a cook where four or five attacks of retention had occurred.

DR. ABBOT had twice been called to cases of sudden inability to pass urine and found a fibroid of the uterus.

DR. CHADWICK said that he was becoming more and more convinced that most cases of bladder trouble yield to general treatment, and that very few require local treatment. An examination is, however, essential in all cases. Caruncle, he thought, existed in a large number of cases without producing symptoms, hence its removal is not likely to give relief where there are symptoms of bladder irritability. There is no more common cause of frequent micturition than retroversion of the uterus, although it is doubtful how it acts.

A recent case he had treated for cystitis when he found the cause to be stone in the bladder, the symptoms were very non-suggestive.

DR. BLAKE thought that the symptom of sudden retention of urine in patients with uterine fibroid may not be so very uncommon, as he had taken care of two such cases, both patients being cooks, and he wondered whether the occupation had anything to do with it. In one of these cases it was necessary to pass a male catheter eight or ten inches before reaching the bladder.

DR. STRONG in closing said that he agreed with Dr. Chadwick that very few cases require local treatment, but that an examination was in all cases necessary. Caruncles he found to be very common in the outpatient department of the Massachusetts General Hospital, occurring in perhaps one out of five patients. The small caruncles just inside the meatus are the ones that give trouble, the large external ones generally give rise to no symptoms.

DR. BLAKE mentioned a case of excessive irritability of the bladder which has lasted for two years, reducing the patient very much. The cause in this case was a urethral caruncle.

DR. GREEN read a paper entitled

THE INFLUENZA EPIDEMIC AS OBSERVED AT THE BOSTON LYING-IN HOSPITAL.³

The reader asked whether any of the members had seen labor brought on by an attack of influenza.

DR. C. E. STEDMAN said he had a patient in the eighth month of pregnancy who had a severe attack of influenza, but it did not bring on labor.

DR. STRONG had a patient who had influenza and miscarried at seven and a half months.

DR. GREEN had a patient with influenza one week before confinement which occurred at the expected time.

DR. EDW. REYNOLDS spoke of cases supposed to be in labor, where it was found that the influenza was the

¹ See page 53 of the Journal.

² See page 57 of the Journal.

³ See page 55 of the Journal.

cause of the pain. One of his cases developed influenza the day after confinement. The baby four or five days later began to cough and have diarrhea, dying in the course of a week. In another case the patient was taken with influenza the day before confinement, and the baby had diarrhea beginning on the second day.

DR. TOWNSEND said that one of his patients had influenza a week before she was confined, and the baby was born with symptoms which lead him to think it had congenital influenza. He would report this case at some future time.

DR. RICHARDSON said that one of his patients had an attack of the gripe at the seventh month of pregnancy and was afterwards confined at the proper time. Another case had a moderate attack of the disease at the seventh and a half month of pregnancy and miscarried on the third day. The infant was feeble, had snuffles and died in three days.

DR. FORSTER reported

A CASE OF EPITHELIAL CANCER IN A NEGRESS.*

DR. STRONG had seen two cases of cancer in colored women in the last month.

DR. EDW. REYNOLDS had met with three such cases.

DR. GREEN showed a photograph of a placenta in a case of triplets. Also a photograph of a man who was born with but the stumps of all four extremities.

AMERICAN NEUROLOGICAL ASSOCIATION.¹

TRAUMATIC NEURO-PSYCHOSES.

DR. G. L. WALTON read a contribution to this subject, in which he dealt exhaustively with the questions of pathology and prognosis in injuries inflicted upon the nervous system by railway collisions and similar accidents. From the influence of Erichsen's views, functional and organic injuries were, for a long time, indiscriminately classed together under the ambiguous and misleading term, spinal concussion, while a common prognosis was given to all, leaving the student in doubt as to whether the worst or best results might be anticipated. To H. W. Page was due the credit of having elaborately corrected this inaccuracy and of sifting out the comparatively rare cases of organic spinal disease, whose sad course and prognosis had been so long allowed to overshadow and include the more common cases in which no demonstrable lesion existed. To the latter class, he had first applied the term traumatic neurasthenia. Dr. Putnam, in 1883, after reporting several cases of traumatic hemianesthesia, had called attention to the importance of looking for evidences of typical hysteria in the chronic as well as in the acute stages of so-called spinal concussion. Among those who had early inclined toward the modified views regarding the effects of trauma on the nervous system, might be mentioned Dr. Dana, who, writing in 1883, had very appropriately added hypochondria to the two terms already applied. Spitzka had considered that spinal concussion could produce spinal irritation. These theories were in direct opposition to the idea advanced by Westphal, that a diffuse sclerosis was set up by the jar. This

view had many followers, both in Germany and America. In a recent work by Chreuger, of Chicago, it was proposed to give to these cases the name "Erichsen's disease." This writer had regarded the spinal sympathetic system as the starting point of the pathological process. Seguin, in "Sajous' Annual" of 1889, considered organic injury to the nervous system a rarity as resulting from the forms of trauma under consideration. Without exhausting the literature of the subject, it might fairly be concluded that there was at present a very general, though not unanimous, tendency to abandon the theory of spinal concussion, and to regard the majority of the genuine cases as identical with already recognized functional forms of disease, rather than cases of organic spinal injury. Dr. Walton's experience had led him from the first to regard disease of the spinal cord resulting from trauma as of comparative rarity, when no dislocation or fracture had occurred, while Seguin's conclusion regarding the preponderance of the subjective symptoms, and the degree in which we were generally dependent on the patients, were fully justified by the majority of the cases which had come under the writer's observation.

The PRESIDENT regretted that the two works dealing with this subject were open to the stigma of having been written for trade purposes. It was important in discussing the question to avoid anything but its clinical aspect.

DR. P. C. KNAPP could not agree with the author of the paper in the position he had taken. Page had deliberately ignored most important neurological points. The theory of Charcot that many of these cases were hysterical was pretty well exploded.

DR. F. F. PUTMAN thought there were but few persons who could carry out successfully a system of deception during a long and searching examination, much less through two such investigations.

DR. F. X. DERCCUM said that in his opinion there was a union of two factors. In some cases there existed actual cause for painful back. It was remarkable how the same story would be repeated unsolicited. It required a person well-trained in the subject to relate such symptoms. Then there would be diminution of the heart-beat, great awkwardness of movement, marked disorders of sensation, errors in locating points of contact, and many other mistakes which a healthy man could not make. Many of these symptoms were such as the patients could hardly pick out for themselves. It was immaterial whether the initial trouble was actual organic disease, or profound functional disturbance, the fact remained that these people did not recover.

DR. W. R. BIRDSALL agreed that it was the most conservative view to say that there was possibly a traumatic lesion in a certain number of these cases, still he thought the great majority showed functional phases. The chief element in the production of these conditions, even if there existed organic changes in addition to the functional disturbance, was emotion, and psychic shock.

DR. D. INGLIS did not agree with the author of the paper. The profession had to take one position or the other in deciding whether these cases were organic or functional, and then a jury might do as it thought fit. He also proposed a method for testing hyper-sensitive areas.

DR. C. K. MILLS thought there were at least three

¹ Report of the Sixteenth Annual Meeting, held at Philadelphia, June 4-6, 1890. Continued from page 42 of the Journal.

* See page 68 of the Journal.

classes of cases resulting from injury: (1) pure fright; (2) cases in which the indications were clear that fracture or haemorrhage or other serious lesion had taken place; (3) cases in which the symptoms presented were both objective and subjective, with a preponderance of the latter. He thought that the existence of some organic lesion, whether myelitis, or the result of hemorrhagic pressure upon some delicate part of the nervous system, would explain many of the symptoms peculiar to this class.

A CASE OF COMPLETE PARAPLEGIA CURED BY TREPHINING.

DR. F. X. DERCUM presented a patient upon whom trephining of the upper dorsal vertebral arches, for paraplegia and complete paralysis of the sphincters, had been performed, resulting in complete recovery.

The PRESIDENT in commenting on this unique case characterized it as almost unprecedented.

DR. PUTMAN said the case seemed to be one of unusual interest, and thought that they must all welcome such advance in the surgery of this region. The speaker had reported several cases, in which he thought exploratory operation might have been done with benefit.

DR. V. P. GIBNEY said he was extremely delighted with the brilliant results in this case. From the way the patient now held his head, he should be inclined to look upon the case as an old Pott's disease. Surgeons had been chary of operating in these cases, though the operation was comparatively an easy one, at least, simple in detail, and with the aseptic and antiseptic methods of to-day, it was practically impossible to have bad results, and recovery was to be expected.

The PRESIDENT said they would be glad to know to what extent the present position of the head corresponded with the position before the operation.

DR. DERCUM said the position was at that time normal. He considered the present inclination of the head forward as due to loss of certain attachments of the trapezius muscles at their points of insertion into the spinous processes. There might have been a rheumatic element in this case affecting the meninges of the cord.

The PRESIDENT said he would like to ask Dr. Gibney as to the deformity in which there was extreme bending forward of the neck.

DR. GIBNEY said this condition sometimes obtained to an indefinite extent. It might be a senile kyphosis. Though it would perhaps be urged that Pott's disease at such an age was impossible, yet as a matter of fact there were quite a number in whom it developed after fifty or sixty, following a fall or injury. The position of this man's head might be due to loss of substance of the bodies of the vertebrae.

DR. W. N. BULLARD thought the rapid advance in spinal surgery should lead to more definite conclusions as to the cases of Pott's disease suitable for operation.

DR. B. SACHS said he was gratified to hear the report of such a case as Dr. Dercum had presented. It went to show that many of the cases hitherto operated upon had been badly chosen. When cases could be selected, statistics would probably be more encouraging and favorable.

The PRESIDENT thought that the theory of rheumatism in this case could not be entirely disposed of.

DR. C. L. DANA said he did not share the optimistic view which Dr. Putman had advanced, and should be sorry to start a boom in spinal surgery. If the history of all the operations already performed in this field was known, he thought they would be disposed to follow the conservative suggestions of Dr. Sachs, and would deal only with selected cases.

DR. GIBNEY said that he did not by any means desire to start a boom in spinal surgery. What he had meant by an easy operation was, that in these old cases of Pott's disease the spinous processes were very prominent, and the soft parts were thin and readily got at. Cases should always be very carefully selected.

DR. DERCUM thought that the proper cases were difficult of selection, and it was only now and then that success could be hoped for. He regarded the results in his case as fortuitous.

A CASE OF LOCOMOTOR ATAXIA ASSOCIATED WITH NUCLEAR CRANIAL NERVE PALSY, AND WITH MUSCULAR ATROPHIES.

DR. FREDERICK PETERSON reported the history of the above-named case. The patient had been under the writer's observation since March, 1890, but the features of the case had been previously described, by Dr. Seguin, in the *Journal of Nervous and Mental Disease* for May, 1888. It was the first of five cases of ophthalmoplegia reported by that author. As there had been so many new developments in the patient's condition during the past four years, that it was thought best to briefly outline the history from the first observations made up to the time when he came under the writer's notice. M. J. T., now thirty-seven years of age, had had a chance and secondary symptom fifteen years ago. In 1882, he had discovered one morning dimness of vision and external strabismus of the left eye, with diplopia. A little later he had shooting pains in the legs, occasionally in the arms. In 1883, he had a momentary loss of consciousness, and fell, cutting his head. His left testicle also became swollen and hard during this year, and he was under specific treatment at Hot Springs for some time. In 1884, he had partial double ptosis. In the right eye, the internal rectus, inferior oblique and sphincter iridis were paralyzed, and the superior and inferior recti feeble. The other muscles were normal. In the left eye the muscles supplied by the third nerve acted variably and feebly. The other muscles were normal. Both pupils were completely motionless to light and accommodation, the left larger than the right. Ophthalmological examination resulted as follows: R. V. = $\frac{2}{3} : \frac{4}{5} W + \frac{1}{4}$. L. V. = $\frac{2}{3} : \frac{4}{5} W + \frac{1}{4}$. R. A. = $\frac{1}{5}$. L. A. = $\frac{1}{4}$. There was no lesion of the optic nerves.

The left cheek was a little inactive, and there was a mild paresis of the right hand. Dynamometer: R. = 42 - 44, L. = 45. No Romberg symptom. Knee-jerks exaggerated. Both feeble and involuntary micturition. In 1885, the ptosis was nearly total on the left, but partial on the right side. In the right eye, the condition of the muscles had remained unchanged, while in the left, they had improved so much that they acted almost normally. Some paresis and atrophy of both temporal and both masseter muscles was now noted. In 1886, when lost sight of by Dr. Seguin, the ptosis was a little greater, the bladder still paretic, and the masticatory muscles unchanged. No

marked facial paresis. The knee-jerks, previously exaggerated, had fallen to about normal. Dr. Seguin, writing in 1888, had said of this case, that some of the symptoms seemed to justify a suspicion of incipient "posterior spinal sclerosis."

Since 1886 until the present time, there had been gradual progress in the disease. The present condition of the eyes was as follows: In the right, all of the muscles external and internal, except the rectus externus, were completely paralyzed. The rectus externus was paretic, and when moved exhibited clonic spasm. In the left eye, there was almost complete ophthalmoplegia *externa et interna*. Both pupils were widely dilated, equal and immobile. Divergent squint of right eye. Vision was unchanged. As far, therefore, as the innervation of the ocular musculature was concerned, we had now lesions affecting both third nerves, both fourth nerves, and both sixth nerves. The weakness and atrophy of the masseter and temporal muscles was more pronounced. These muscles did not react to Faradism. There was no anesthesia of the face. The tongue deviated slightly toward the left. The electrical reactions in the face and tongue muscles were normal. There was still some evidence of weakness in the right hand. The patient had now well-marked tabes dorsalis. There was marked ataxia of all four extremities. He could not walk without assistance. The knee-jerks had disappeared. There was numbness, anesthesia and analgesia in all of his fingers. In both legs, as far as the knees, there was almost complete tactile anesthesia. Muscular sense was entirely lost in both feet. In addition to other symptoms, which pointed out fully-developed locomotor ataxia, the patient presented some very interesting trophic disturbances. Beside that of the muscles supplied by the motor branches of the trigemini already described, there was wasting of the right trapezius, with a degenerative reaction. In the left upper extremity there was complete paralysis of the two long extensors of the phalanges of the thumb, and atrophy and paresis of the abductor minimi digiti and of all of the interossei and lumbricales, with degenerative reaction. On the right side there was almost complete atrophy of the opponens and abductor pollicis. Considerable wasting was apparent in the adductors of both thighs, more upon the right side.

The main features of the case might be summarized as follows: The patient had had a number of bilateral motor cranial palsies, namely, the third, fourth, fifth and sixth nerves. He had also exhibited slight traces of crossed paralysis for more than four years. Locomotor ataxia had been developed, as was shown by the occurrence at one time of lightning pains, and by the presence now of ataxia, widely distributed anesthesia, failure of knee-jerks, and ocular, vesical and anal symptoms. Finally, he had presented marked trophic changes in numerous muscles. As to the morbid processes underlying these various manifestations, there was in the first place undoubtedly a sclerosis of the posterior columns of the spinal cord. The ophthalmoplegia was, of course, nuclear. Read in one way, the symptoms on the side of the cranial nerves, taken in conjunction with the muscular atrophies and paralyses elsewhere, certainly very closely resembled the syndromes so well described by Dr. Sachs in a paper last year under the title of "Polio-encephalitis Superior, and Polio-myelitis." The most important matter to be settled in this case was whether the muscular

atrophies were due to peripheral or central lesions. Speculation upon the question would seem to be of very little utility, and its solution must be left to the hoped-for autopsy. It had been assumed by a number of authors that total paralysis of all of the muscles supplied by the third nerve, implied not a nuclear but a nerve-trunk palsy. In the writer's case all of the muscles of both third nerves were totally paralyzed, including both irides; and yet there was every reason to believe that the palsies were nuclear. It would at least be difficult to conceive of a lesion at the base of the brain so widely affecting the trunks of the third, fourth and sixth nerves, and the motor portions of both trigemini, yet permitting the escape of the sensory portions of the latter.

DR. C. K. MILLS thought that the case might be some peculiar, irregular form of syringo-myelia.

DR. E. D. FISHER suggested that the case was one of amyotrophic lateral sclerosis.

DR. SACHS thought the case very closely resembled one of his, in which the diagnosis was polio-encephalitis superior and polio-myelitis, although there were more symptoms of tabes dorsalis than in his case.

DR. PETERSON did not think the case one of syringo-myelia owing to the very symmetrical distribution of the nuclear palsies, and because there was no anesthesia of the upper extremities, face or trunk.

MULTIPLE NEURITIS, OR BERI-BERI, AMONG SEAMEN.

DR. J. J. PUTNAM reported about twenty cases of a disease resembling beri-beri, but possibly another form of multiple neuritis, occurring among fishermen in northern latitudes, and referred to a similar series of cases reported by Dr. F. C. Shattuck in 1881. By correspondence with physicians in the sea-port towns, Dr. Putnam had ascertained that, besides the larger epidemics, sporadic cases occurred from time to time. One physician had reported frequent cases of swelling and numbness of the hands attributed to handling fish. The influence of alcohol and the metallic poisons could be excluded; and since the outbreak occurred only now and then, the influences to which the seamen were habitually exposed could hardly be considered as the whole cause, though insufficient food had seemed to play a part in some instances. Most of the patients had recovered, but some had died.

DR. GRAY asked if these men carried large quantities of ice, because he had seen neuritis following the handling of ice, which had promptly subsided if this cause was removed.

DR. BIRDSELL asked as to the amount of air supplied to the hold of these vessels and to the seaman's quarters. Cases recently reported to him had led to the impression that the men who had died had been especially exposed to bad air in the hold, while those in good quarters had escaped. He agreed also that cold was an important element in the production of nearly all forms of neuritis.

DR. HEUTER asked if the diet had been of fish.

DR. PUTNAM said that fish had not been the diet, but salt pork, sometimes fresh vegetables and fresh meat. But in one of the worst cases it had been salt pork.

ON CASES OF POSTERO-LATERAL SCLEROSIS, WITH SPECIAL REFERENCE TO THE PATHOLOGY OF THE DISEASE.

Dr James J. Putnam referred to a series of eight cases of similar character, presenting the symptoms

of "combined sclerosis" of the spinal cord, which he had seen during the past few years, and reported four of them, in which he had examined the cord microscopically. All the cases of the series, though differing in some respects, resembled each other as follows: all the patients were past middle life; all were either anaemic or in a state of poor nutrition. The symptoms in all had consisted in both motor and sensory disorders in all four limbs, sometimes associated with incoördination, sometimes not. The knee-jerk was exaggerated in all but two or three; in those it was absent. Tabetic pains were present in one case only. Anatomically sclerosis was found in the posterior and lateral columns, varying in exact position. In almost every case the posterior change had seemed the older and most intense. Besides the "typical" sclerosis, there was evidence of a more recent process, characterized by granule-cell formation, and the breaking down of the nerve-tubes so as to form circular or oval spaces. This new process was developed on the borders of the older change. The gray matter of the cord was more or less affected, and the nerve roots in about the same degree. The cases had all run a rapid course, terminating, after one to four years, in death, preceded by paraplegia due to non-inflammatory softening. Next to inherent structural weakness, as an etiological factor, came impaired nutrition and toxic influences. The importance was pointed out of recognizing, and attempting to meet, the partial courses of the disease, of which several might be present at once. As special stigmata of degeneracy in these four cases, the writer referred to the mental condition and family history of several of the patients; to the remarkably abnormal shape of the cord in one; to the small size of the dorsal gray matter in another, and the presence of a second central canal in a third.

DR. S. G. WEBBER cited the case of a young girl, who, from excessive walking, had developed decided symptoms of lateral sclerosis. This patient had gradually recovered the use of her limbs.

DR. PUTNAM, replying to Dr. Dereum, said that there had been no serious involvement of the internal organs in any of the cases and no typical Bright's symptoms. These patients were so largely women that he could not but assume the existence of some lesion from impaired nutrition and constitutional taint.

THE PATHOLOGICAL FINDINGS IN DR. W. A. HAMMOND'S CASE OF ATHETOSIS.

DR. G. M. HAMMOND read a report on the pathological findings in the original case of athetosis on which Dr. W. A. Hammond's description of athetosis was based. After briefly referring to the case, Dr. G. M. Hammond stated the portion involved in the lesion had consisted of fibrous connective tissue. Topographically the lesion was a lengthy one in the antero-posterior direction, parallel in its short axis with the internal capsule. Its posterior end had invaded the stratum zonale of the thalamus on its posterior third and the posterior half of the internal capsule. In its anterior extension it had crossed the capsule, invading the posterior third of the outer articularis. The author called attention to the fact that the motor tract was not implicated in the lesion, and argued that this case was further evidence of his theory that athetosis was caused by irritation of the thalamus, the striatum or the cortex, and not by a lesion of the motor tract.

DR. E. C. SPITZKA reported a case in which the

lesion was found to be in the same situation as in Dr. Hammond's case.

DR. E. C. SEGUIN presented a paper on

ATHETO-CHOREIC SPASM OF THE RIGHT SIDE OF THE BODY.

The post-mortem had shown a glioma of the left thalamus opticus and adjacent internal capsule. Dr. Seguin's views were that all cases of athetoid and choreiform movements following hemiplegia were due to lesions involving the thalamus and adjacent capsule.

THE NEW YORK ACADEMY OF MEDICINE.

STATED MEETING May 15, the President, ALFRED L. LOOMIS, M.D., in the chair.

DR. L. L. SEAMAN, read a paper on

THE AUSCULTATORY PERCUSSOR.

This is an instrument constructed on scientific principles, by which, as explained by him, the practitioner is enabled to realize and delicately discriminate the percussion note, while adding to ordinary percussion the value of mediate auscultation; thus securing a trustworthy and explicit tonal reading of internal conditions. In conjunction with the Edison phonograph it also furnishes an instrument by means of which percussion notes may be accurately registered. When in use the object end of the instrument is placed directly over the area under examination. The thumb raises a lever which, when at a given height is released, the action of a strong spring throwing the hammer at its extremity vigorously down upon a flexi-metre. The hammer works in a bell-shaped receiving-chamber, and the impulse thus imparted forces the air into sonorous undulations, which, after deflection along the walls of the chamber, are propagated without dispersion to the ears of the listener by means of binaural tubes modelled after those of the Camman stethoscope.

DR. ROBERT ARBE, read a paper on

SPINAL SURGERY: A REPORT OF EIGHT CASES.

These cases, he said, had all been subjected to prolonged medical treatment, and when referred to him were in almost a hopeless condition. Almost as many more cases had been refused operation; but these seemed either to offer hope of relief based on experience, or to give legitimate opportunity for novel operative methods based on sound physiological principle. The spinal cord had been regarded as more inaccessible to the surgeon than the brain, and it was from the ranks of the doomed cases of paralysis of the lower half of the body, and some other spinal troubles that an effort was being made to call out more cases which, heretofore neglected, might yield good results.

Having referred to the articles published by White, Winslow, Bennett, Horsley, MacEwen, Thorburn and others, he said it was evident that some cases of improvement had been reported prematurely. The need of reporting carefully all cases where operation was done had led him to present his eight cases. These might be divided into four groups: three cases of paraplegia from fracture, one of early curetting of a vertebra for Pott's disease, two of tumors of the

vertebral canal with paraplegia, and two of intradural section of some of the posterior roots of the brachial plexus for neuralgia.

CASE I. Fracture of the spine between the eleventh and twelfth dorsal vertebrae: complete paraplegia and anesthesia. Operation eleven months afterward; breaking up intra-dural adhesions; suture of dura; primary union. No relief of paralysis up to one year afterward.

The patient was a merchant twenty-seven years of age, who fell from a platform twenty-one feet high May 19, 1888. He was unconscious for three hours, and was completely paralyzed, and insensitive below the waist when he recovered. After three months he resorted to a wheel-chair, and attended to business. In April, 1889, he was brought from Texas, where he resided, to Dr. L. A. Sayre, who referred him to Dr. Abbe. The operation was performed April 12th. The back was shampooed the evening before, and a damp, sublimate dressing kept applied until the moment of operation. The patient having been laid prone, but with one shoulder raised by a sand pillow, a free incision was made parallel with the spines and half an inch to one side, cutting the longissimi attachments from one side only, and being carried clean down to the laminae at the second or third pass of the knife. To approach the fracture, the incision was made from the eighth dorsal to the first lumbar spine. The laminae were now cleared of muscles, which were drawn outward by retractors, and the ligament divided above the spine of the eighth and below the eleventh; thus isolating a block of four spines, whose bases were then severed from their arches by stout cutting pliers. This manoeuvre at once allowed a retraction of the entire block of connected spines with their muscles still attached on one side, and the entire breadth of the spinal arch was thus exposed without sacrificing the overlying tissues. A pair of slightly curved rongeurs was now applied to the lower edge of one lamina, and with incredible ease the entire breadth was quickly gnawed away. Three arches, the tenth, eleventh and twelfth, were thus treated, and the clean spinal cord laid bare for two and one-half inches.

The twelfth dorsal vertebra was found to have been displaced backward, the fracture running through the articular facets, the pedicles and the laminae, and the cord was compressed between the arch of the eleventh above and the upper lip of the body of the twelfth below; while the intervertebral cartilage had been ruptured. Above the line of fracture, the cord pulsated; below, it did not. In half a minute after the cord was released from its flattened state (the bone-pressure area being only half an inch deep), the dura became rounded up as full as it was above or below. The wound now being irrigated and dried, the dura was slit up for two inches. Adhesions of various density were found within, attaching the meninges to the dura, and forming a complete circular dam, which shut off the upper from the lower part of the canal. Only an ounce of clear spinal fluid came out, as the spinal cord had purposely been inclined on the table so as to slope with the head lower. The adhesions were broken up with very little force. The cord was normal in thickness above the involved part; then by a sloping, rather than abrupt change, it merged into a flattened cord for three-fourths of an inch, retaining its breadth, but less than half its thickness. The principal atrophy seemed to be in the posterior col-

umns. Throughout this flattened portion the white fasciculi of the cord could be traced continuously; so that there was no abrupt break in its continuity.

The affected portion of the cord proved too extensive to render it possible to attempt to excise this and suture the fresh cut ends (a procedure never yet accomplished); but to judge whether such a thing would ever be possible, Dr. Abbe tried to approximate the sound end on either side of the damaged part by traction made with tenacula embedded in the meshes of the membranes at such points as would have been available for sutures. There being a slight latitude of motion of the cord vertically in the canal, he judged at this trial that he might have excised a scant quarter of an inch, and then approximated the ends by sutures that would not tear out. The damaged cord in this case was three times that length.

No further repair being possible, the dura was sutured by fine cat-gut. Then the displaced spines were brought into line and sutured by heavy cat-gut to their neighbors above and below. The fascia investing the muscles next received two or three interrupted cat-gut sutures, with gaps for drainage, and finally the skin was drawn partly together by a few cat-gut sutures, not tied but left for use at the next dressing. No drainage-tube was applied, but a piece of protective three inches wide was laid on the wound; the skin edges being left a quarter-inch apart so as to allow drainage. The investing antiseptic dressing was covered by a plaster jacket covering only the back, like a turtle shell, and secured by an enveloping Canton flannel binder pinned in front. In forty-eight hours the dressing was changed. Drainage had been perfect, and the wound had healed except the skin, which the sutures already in place now brought together when tied. A final dressing was then put on, and the wound healed primarily, leaving only a linear scar. The patient's condition has been watched since then and there has been no improvement in motion or sensation.

CASE II. Fracture of spine at the eleventh and twelfth dorsal vertebrae; paraplegia. Operation after two and one-half years.

This patient was also twenty-seven years of age. In October, 1886, he was thrown from his horse on his ranch in Montana and struck his back across a stick. Instantaneous and complete paraplegia resulted, with paralysis of the rectum and bladder. He lay for a day and a half where he fell without food or drink and exposed to sleet and snow. As soon as he was discovered he was taken to a farm-house, where, as a restorative, bottles of hot water so hot as to cause blistering were applied to his feet; and the blister resulted in gangrene. After three weeks he was removed to his home in Connecticut, where it was found necessary to amputate both legs below the knee. His general health afterwards improved to such an extent that he was able to be placed in his carriage and drive about; but a few months before he came under Dr. Abbe's care gangrene of the buttocks had resulted from his unwisely remaining in his buggy for about seven hours. His condition thus became desperate, and he was brought to New York in the hope that some method of operation might be devised for his improvement.

He was examined by Dr. C. L. Dana, whose conclusion was that the cord was absolutely severed at the last dorsal, but that below the second lumbar it

must be in fairly healthy condition. The case seemed absolutely hopeless unless it was possible to innervate the lower segment of the cord by renewing its contact with the upper, or what seemed not impossible and perhaps worthy of trial, by carrying out a suggestion of Dr. Dana, in case the parts were not too much injured, to cut off a few of the lower dorsal roots long and the lumbar roots short, and suture them together, thus increasing the chance of getting sensation. On April 18th, 1889, the same procedures were adopted as in the preceding case, and it was found that a massive and dense eburnated deposit of bone had formed at the site of the eleventh and twelfth dorsal and first lumbar laminae. This was with difficulty chiselled and cut away until the severed end of the spinal cord was exposed. Below this for one and one-half inches solid bone filled the vertebral canal, and beyond that the cord commenced again. Its end was found engaged in the bone so that spicule had grown into it; and it was evident that repair by suturing was hopeless. The patient lived for only thirty hours after the operation, and during this time but four ounces of urine were secreted.

CASE III. Fracture of the twelfth dorsal vertebra; paraplegia. Operation. Recovery unimproved.

The patient, who was of the same age as the other two, in alighting from a street car on January 1, 1889, was struck in the small of the back by the rear platform of the car. He fell on his hands and knees, suffered acute pain in the back, and at once became paralyzed. He was operated upon on February 28, 1889. The arch of the eleventh dorsal showed evidence of recent fracture, but there was no displacement and no pressure. When the dura was exposed, it appeared evenly full and round, and as far as its surface showed, nothing would have been suspected wrong within it. It was, however, slit for three and one-half inches, and from the lower part of the opening a little fluid escaped. At a point underneath the injured arch a circular dam of lymph was found, one-eighth of an inch wide, between the dura and the cord, entirely shutting off the upper from the lower part of the canal; and from above this dam the arachnoid fluid flowed freely. The cord at this point showed evidence of having been completely crushed, the white substance ending abruptly and beginning again something over half an inch below. In the intermediate space the cord was represented by a pinkish gray substance apparently consisting of only the meshes of the membranes. Just below the lymph dam a mass of largely distended veins occupied the surface of the cord, showing obstructed venous return. These entirely emptied themselves upward when the pressure was taken off and the lymph parted by the probe. The cord was entirely liberated from its adhesions, the dura sutured with fine cat-gut, and the wound closed. A temporary hyperesthesia of the paralyzed parts resulted from the operation, but there was never any voluntary motion, and the patient soon relapsed into his former condition.

In commenting on these cases Dr. Abbe said that all operators upon cases of fracture paraplegia of any duration have thus far arrived at about the same conclusion, namely, that the pressure of bone is of the most secondary importance, except the fracture involves only the arch, where it is driven in by a blow; inasmuch as the violence which will produce instant paralysis has done so by a diastasis of the vertebrae, the

cartilage being ruptured and the arches broken, which completely pulpitizes the spinal medulla. The vertebrae are very apt to immediately resume their usual relations. If, however, the fracture takes place at or below the last dorsal, where the medulla is replaced by the cauda equina, the crushing does not usually destroy the nerves; though long pressure would. In such case operation to correct it is always desirable. It still remains a problem, perhaps never to be solved, how to connect the lower segment of the cord with the upper, when there is a gap of half an inch, and whether this union would restore functional connection with the brain, even though its reflex and independent activity may be ever so good.

CASE IV. Pott's disease taken early and treated as a tubercular caries in one of the joints.

The case was narrated to show the ease with which the vertebral bodies, if carious, may be approached from behind. The patient was twenty years old. A probe inserted into a sinus resulting from a lumbar abscess passed upward to the last dorsal vertebra. An incision, guided by the probe, was made beside the twelfth dorsal. It was found that the transverse process of the vertebra was carious and it was cleared away with a bone curette, which was then worked into the body of the bone alongside the spinal dura, without injury to the latter. A large excavation of softened bone was removed (to the extent of about half of one vertebral body), and the curette then encountered firm and apparently sound bone. The entire course of the pus track through the soft parts was curetted and douched with sublimate solution, and finally with solution of iodoform in ether.

(To be continued.)

Recent Literature.

Transactions of the American Surgical Association.
Vol. VI. Edited by J. EWING MEARS, M.D., Recorder. Cloth, pp. 572. Illustrations and Plates. Philadelphia: P. Blakiston, Son & Co. 1888.

This volume contains, besides a full report of the transactions of the 1888 meeting, a list of the officers and members, the president's address, and reprints in full of the papers read, with the subsequent discussions. The list is too extensive to enumerate separately these interesting contributions, which are already well-known, from the pages of the principal medical journals, and subsequent publication of many as separate monographs. They are all of worth, but those of Senn, Keen, Packard, Bull, Gay, Willard, Cheever and Park have apparently attracted the most attention and interest. The work of the recorder and publisher has been excellently done, and this elegant volume, as has already been fittingly said, is one "distinctly a credit to American surgery."

Suggestive Therapeutics: A Treatise on the Nature and Uses of Hypnotism. By H. BERNHEIM, M.D., Professor in the Faculty of Medicine at Nancy. Translated from the Second and Revised French Edition by CHRISTIAN A. HERTER, M.D. Octavo, pp. xvi, 420. New York and London: G. P. Putnam's Sons. 1889.

Bernheim is to-day the acknowledged leader of the so-called Nancy school of hypnotism, and the volume before us is his own presentation of the doctrines of

that school. As is well-known, Bernheim is the disciple of Liébault, the founder of the school, and he has taken strong ground against the views of hypnotism presented by the school of La Salpêtrière. Bernheim's first chapter is devoted to the methods of hypnotizing, and a classification of the stages of hypnotism. His method is strictly by verbal suggestion. To this, he claims, the majority of people are susceptible. In a single year only 27 out of 1,012 patients proved wholly refractory, and, he adds, "it is wrong to believe that the subjects influenced are all weak-nerved, weak-brained, hysterical, or women. Most of my observations relate to men." He classifies the stages in two great divisions, according as memory is or is not preserved on waking: masking nine classes, all told, from mild somnolency to states in which hypnotic and post-hypnotic hallucinations can be produced with amnesia on waking. This chapter is followed by four chapters giving careful details of the various physical and psychological conditions which may be present in the hypnotic state, a chapter against the doctrine of Charcot, an historical chapter, and two chapters devoted to expounding his own theory of hypnotism. The second part deals with the therapeutic use of hypnotism, with the histories of 105 cases in which it was used with greater or less success.

Bernheim maintains stoutly that the manifestations of hypnotism are due solely to suggestion, "the influence exerted by an idea which has been suggested to and received by the mind." That the automatic condition thus produced is not abnormal is shown by the many automatic acts which we daily perform. In many of the cases, consciousness and will exist, in others, they are diminished or lost. There is, however, "exaltation of the ideo-motor reflex excitability, which effects the unconscious transformation of the thought into movement, unknown to the will," or of the ideo-sensorial reflex, transforming thought into sensation or into sensory image. "Sleep itself is born of a conscious or unconscious suggestion." Suggestions to be carried out after a long interval (*suggestions à longue échéance*) are due to latent memories (unconscious cerebration), such as those which enable us to awaken at a fixed time. The three stages of Charcot, lethargy, catalepsy and somnambulism are due solely to suggestion, and are not natural phases of the hypnotic state.

The therapeutic action of hypnotic suggestion is, if we may accept Bernheim's results, something remarkable. Contracture in hemiplegia and hemianesthesia from gross lesions of the brain, ulnar neuritis, pressure paralysis from fracture of the spine, myelitis, rheumatism, the pains of tabs, all forms of functional neuroses, gastritis, neuralgias, disorders of menstruation, all yield to suggestion; while bad results are never seen. "When it is well managed, it does not produce the slightest harm." "Hypnotic sleep in itself is beneficial, and is free from harm as is natural sleep." The only risk is in producing post-hypnotic hallucinations.

Such is the position that Bernheim takes in regard to hypnotism. It is certainly a question how far his views may be accepted. There is still much to be said in favor of the school of La Salpêtrière; this, first of all, that it is composed of men trained in dealing with nervous phenomena, and, therefore, better able to appreciate them. The cases of *grande hystérie* are certainly rare, but our knowledge of hysteria has received more light from the study of the pronounced phe-

nomena in these cases than from the study of the much commoner mild hysterical symptoms. So of organic diseases, our knowledge must be based first on the study of pronounced and typical cases before we can appreciate the slighter and more transient phenomena. The same must be said of hypnotism; the pronounced forms are to be seen only in the hysterical. The study of these cases will afford us knowledge of the type. Some of the milder symptoms, as Charcot has repeatedly admitted, can be obtained in many subjects; but the work of Charcot has given us definite knowledge in the light of which these abortive cases can be studied. The study at La Salpêtrière, as described by Richer, bears evidence of careful control and a scientific investigation; it has, moreover, been in part corroborated by the independent and thorough work of two eminent Italian observers, Tamburini and Seppilli, whose work has received too little attention in this country. They have established that the phenomena of hypnotism are not due, as Bernheim claims, solely to suggestion, but that they can be produced by purely mechanical means. This view is strengthened by the fact that animals can be hypnotized; here suggestion can hardly be called into account.

It is, moreover, an untenable position, in the light of our present knowledge, to hold that the hypnotic sleep is practically the same as natural sleep. Physiological research shows some analogies, but also marked differences in the circulatory, respiratory and reflex phenomena. Sleep itself may be born of a suggestion, and Bernheim's explanations of the way suggestion works in producing normal sleep are very beautiful, but the unimaginative mind fails to discover the part suggestion plays in producing slumber in a six-hours-old baby or a week-old kitten.

It certainly requires great credulity to accept the marvellous therapeutic benefits which Bernheim and some of his followers claim. The chances of self-deception on the part of the physician, and of conscious or unconscious deception on the part of the patient are great, and time alone can prove how many grains of salt are to be added to the prescription of suggestion. It renders us the more sceptical to find that the leading neurologists who have studied hypnotism claim far less than do the few "hypnotologists" of France who follow the professor of Nancy. The dangers, too, which Bernheim slighted are certainly not to be ignored. Cases of grave, nervous disturbance following hypnotism are not rare, and they rest on good authority; minor disturbances are probably still more common, and many observers have called attention to them. It is too early yet to pronounce definitely as to the future of hypnotism. It has added somewhat to our psychological knowledge. It has some therapeutic results to boast of, but whether it can give better, safer and more permanent results than our other measures of relief is still very doubtful. Except with a few enthusiasts, it seems already to be on the wane, and another decade will probably see it in its true place.

To all interested in the study, however, Bernheim's work will appeal, for it is the gospel of the Nancy school, and as such, it demands the attention even of those who dissent from its doctrines. The translation has been well done, but it is curious to find a New York man following the error of the original in speaking of the late Dr. Beard as "of Boston."

RECENT VIEWS AS TO INFLAMMATION.

THE microbial doctrines of the present day have completely changed prevalent notions as to the nature and purport of inflammation. Formerly it was taught that inflammation was the result of a local irritant causing an excessive afflux of blood to the part with vascular paralysis and exudation; this might be produced by a foreign body, as a thorn, a splinter of glass; it might be due to a poison in the blood, that is, some hypothetical fever poison, or *materies morbi* generated by cold. With the progress made in microbiology the past twenty or twenty-five years, the number of inflammations, clearly not of bacterial origin, has been greatly reduced; some authorities, as Gerster,¹ affirm that microbes are the *sine qua non* of all inflammations.

Even the "idiopathic" inflammations such as acute pleuritis, meningitis, etc., would be explained by these writers as being of parasitic origin (tuberculous or rheumatic, etc., even rheumatism being regarded as an infectious disease).

A popular hypothesis a few years ago was that inflammation is an abnormal nutritive process, the nutrition of a part being exaggerated and perverted under the influence of an irritant. This was afterwards modified or supplemented by the theory of alteration of the blood-vessels, this favoring stagnation, diapedesis, and exudation. Still later experimental investigations have greatly lessened the importance of the rôle to be attributed to ordinary irritants. The classic "thorn in the flesh," if perfectly aseptic, is rather harmful by interfering with the function of the part and by pressure on nerves, than by exciting inflammation or suppuration, which it does not do if all germs are rigidly excluded. Instances are cited² where foreign bodies, as well disinfected steel nails, the point of an aseptic knife-blade, a piece of glass perfectly clean, etc., have been imbedded in the tissues for weeks without causing any inflammation, or any great inconvenience. Even dead organic substances taken from a

freshly killed animal (blood, bits of muscle, tendon or bone) have been introduced into the abdominal cavity of animals under strict antiseptic precautions. "The animals being killed, it was found that blood was absorbed outright; that muscle, liver, tendon and bone were encapsulated; and that their structure was gradually invaded by granulation tissues, disintegration and final absorption following after a while, proportionate to the density of the implanted bodies."

The author from whom we have quoted alludes to a remarkable experiment of Tillman performed on a rabbit, in the abdomen of which an entire rabbit's kidney was deposited without causing any harm whatever. After forty-seven days the implanted kidney was sought for in vain, as it had disappeared by absorption. It is quite certain that if in these cases the ordinary aseptic measures had been omitted, septic purulent peritonitis would have followed.

With regard to chemical irritants, while there has not been uniformity of results among experimenters, careful and painstaking workers, like Klemperer and Scheuerlen, have found that when substances such as croton oil, turpentine and bits of glass, rendered perfectly aseptic, are antisceptically introduced under the skin of animals no suppuration has ever followed. "Small quantities caused some exudation of plasma, and then were absorbed outright." The fragments of glass "were found imbedded in a film of new formed connective tissue." Large quantities of croton oil, "caused a coagulation necrosis of a limited mass of tissue which was found dense, bloodless, and of a yellow color." These nodes of necrosed tissue were gradually absorbed, "suppuration never following the experiment."

As for the nature of inflammation, this is explained as follows — and here again we cannot do better than follow Gerster's lucid statement:³

"An injury of some kind has devitalized the tissues of a certain region, and these become a favorable pabulum for micrococci. The living tissues around still offer a decided resistance to the invasion of the microbe. Bacteria cannot thrive on the products of decomposition they need for their sustenance dead, but undecomposed albuminoid substances. As soon as the supply of dead animal tissue is exhausted the microorganisms starve and perish,⁴ while the spores are left behind, dormant. We will suppose the injury, resulting in the inflammation, to have been a wound; this has destroyed the vitality of those cells that lie in the direct path of the cutting implement. The blood and lymph exuded from the vessels coagulate and also represent dead matter.

"If a number of active micrococci are implanted into the bottom of the wound, they will at once multiply, using the blood-clot and its extensions into the blood-vessels, together with the adjacent dead or devitalized tissues, as welcome soil for their development. This fermentative decomposition produces from the very beginning certain poisonous alkaloids, ptomaines,

¹ *Ibid.*, p. 114.

² We do not understand the author of "Aseptic and Antiseptic Surgery" to advocate the extreme view that all inflammations are necessarily microbial; he certainly, however, teaches that all external inflammations are so.

³ *Aseptic and Antiseptic Surgery, 1888.*

⁴ See Gerster, *loc. cit.*

that are very diffusible. These have a toxic influence on the adjacent vaso-motor nerves, causing their paralytic dilatation; hence the active hyperemia, the *rubor*.

"The blood, passing through the adjacent arterioles and capillaries seems also to become altered; the red corpuscles become packed and finally stagnate in the smaller vessels. The walls of these vessels, including the veins, lose their impermeability, and there is emigration of the leucocytes and even of the red corpuscles into the surrounding tissues; hence the *swelling, tumor*.

"Chiefly as a consequence of the increased blood-supply, a marked increase of the local temperature is observed — *calor*. Direct pressure caused by the dense infiltration, and the actual destruction of the nerve tissue, perhaps also, in some measure, the immediate influence of the ptomaines on the sensory nerve filaments of the part, give rise to *pain*, the *dolor*.

"Stagnation and dense infiltration finally produce a very high degree of tension, leading to compression of large afferent vessels. The infiltrated portions, devitalized by suppression of the normal circulation readily succumb to the invasions of the millions of micro-organisms, and actual necrosis rapidly follows. The last stage of textural destruction is the final liquefaction of the tissues and infiltrating leucocytes, aided by the exudation of large quantities of lymph serum from the adjacent unobstructed blood-vessels, and thus we have the formation of an abscess, or a cavity filled with lymph serum, dead leucocytes (pus-cells) and shreds of necrosed tissue.

"The veins also participate in the disturbance, and coagulation of their contents — *thrombosis* — takes place, and adds to the existing stagnation."

In accordance with the explanation above given, any considerable extension of the septic process and absorption of the ptomaines into the general circulation produces those formidable accidents known as septic fever and pyæmia.

Such, in brief, is the latest teaching — by no means yet accepted by all pathologists — according to which the only phlogogenic irritant and pus-generator is the baneful microbe.

COATS OR SHIRT-SLEEVES?

To what extent the minimizing of raiment shall be carried during the summer months by those who are "off duty," and in the security of their own domiciles, will depend, of course, entirely on the fancy of each individual thus fortunately situated. But upon those who, in a business or a social way, mingle with their kind, obvious limitations are imposed. The most superficial observation will show that the prevalent methods of hot-weather dress have improved in reasonableness of late years, with the increasing development of various forms of "outing." Some very unnecessary comment was caused a year or two ago, during the hot weather, by the fact that certain United States senators appeared in their seats clad in flannel shirts. This summer a prominent Massachusetts congressman did not hesitate to wear in the House the *sash-and-no-waistcoat* garb which was comfortable and appropriate to the street. Yet another Massachusetts

member has gone so far, in the course of a debate in the House, as to take off his coat altogether. It is said that the Speaker, whose ideas of prerogative have never been considered to lack virility, has, perhaps from his own stalwart person being wilted by the vertical rays of Washington sun, so far yielded from his ordinarily uncompromising attitude as to intimate mildly that he hoped the members who contemplated taking part in debate would, at least, keep their trousers on.

And now the Memphis Cotton Exchange has been aggravating its already high temperature by a heated discussion as to whether the members of that board shall be allowed to do business in their shirt-sleeves. A strong conservative sentiment has developed, which seems likely to carry the day.

Sociology should have its word on this subject as well as climatology. A coat is a coat, for purposes of civilization; and when it can be as easily constructed of seersucker or pongee as of broadcloth, there seems little excuse for a gentleman's letting go of it altogether in public. If the National Congress and the Memphis Cotton Exchange do not stand firm on these points, the infection may spread, for aught we know, till it invades the pulpit and the Supreme Bench of the United States.

MEDICAL NOTES.

— The President last week transmitted to Congress a communication from Secretary Blaine announcing the action of the International American Conference regarding the better protection of the public against contagious diseases. Secretary Blaine in his letter says:

"The sanitary officers of the Gulf cities of the United States have hitherto found great difficulty in protecting the public health against contagious diseases brought by shipping from South America, Central America, Mexico and West Indian ports, without restricting the freedom of commerce. At certain seasons of the year the quarantine regulations, which they have been compelled to adopt, have often placed an absolute embargo upon communication with the tropical countries where such diseases originate. The same difficulties have been experienced in a like measure by the neighboring nations, and the attention of sanitary specialists, both in Europe and America, has been for years engaged in the task of devising some remedy.

"International sanitary conventions were held at Rio de Janeiro in 1887, and at Lima, Peru, in 1889, and were composed of eminent scientists who gave the subject the closest investigation. At both these conventions regulations were framed for the protection of shipping and of ports exposed to infections, which agree in all their essential provisions. Those of the convention of Rio de Janeiro were adopted by Brazil, Paraguay, Uruguay and the Argentine Republic, and are now enforced in the ports of those nations. The recommendations of the Conference have not been carried into effect. Colombia, Venezuela, and the

nations of Central and North America were not represented at either convention, but they are equally interested in securing the results desired, and the International American Conference recommends the acceptance and enforcement by them of the regulations of the Rio de Janeiro Convention, or those adopted at Lima, as the best systems that have yet been devised."

— The Alvarenga prize of the College of Physicians of Philadelphia, consisting of one year's income of the bequest of the late Señor Alvarenga, of Lisbon, has been awarded to Dr. R. W. Philip, of the Victoria Dispensary for Consumption and Diseases of the Chest, Edinburgh, for his essay on "Pulmonary Tuberculosis," which will be published by the College.

— It is said that the summer practice of Philadelphia and New York physicians at watering places on the New Jersey coast is seriously interfered with by the new medical law which went into effect in New Jersey, July 4th. By this statute every physician seeking to practise within the State's limits after its passage, must submit to a formal examination by State officers. Exempted from the provisions of the law were "commissioned surgeons of the United States army, navy or marine hospital service, or regularly licensed physicians or surgeons in actual consultation from other States or Territories, or regularly licensed physicians or surgeons actually called from other States or Territories to attend cases in this State."

Physicians called in consultation or those summoned to attend a special case were thus relieved of the necessity to pass an examination, but not so with the scores of doctors of Philadelphia and other cities who yearly settle at the seashore for the summer, and take up regular practice. The latter must be examined. A very few were forehand enough to register under the old law before the new went into effect, and so become practically New Jersey physicians, on going through the necessary formula just in time. It is now found that out of over 2,000 practising physicians in Philadelphia, many of whom practise in New Jersey during the summer time at least, only 150 at the most have registered in New Jersey.

— Another member of the British Peerage, the daughter of the Duke of Sutherland, has gone in for a course of training in nursing, having enrolled herself for that purpose in one of the London hospitals.

— *Druggist.* — "I don't see why we should be expected to sell postage stamps. They're not in our line."

Brown. — "Of course they're not. When you run out of them you can't give anything else as a substitute." — *Lippincott's Magazine.*

— Investigations recently made appear to show, as reported by a lay contemporary, that the lead-miner does not really suffer in health more than any other worker under ground, as the ore is not in a condition to be absorbed by the body, but that lead-smelters and all engaged in the manufacture of lead, particu-

larly white lead, run a very great risk of being contaminated sooner or later. It also appears that at Tyne-side, the chief centre of the English lead trade, there is one type of ailment which is rarely seen elsewhere, attacking those who have been engaged in the work only a few months, or even weeks — a fatal disease, the principal victims being girls of from seventeen to twenty-three years of age. They rapidly display symptoms of this form of toxæmia in the way of severe headache, followed by colic, blindness, and, unless they speedily leave work for a considerable period of time and undergo most careful treatment, the fatal result is rapidly ushered in, usually with epileptiform convulsions and coma. It is remarkable, however, that but little trace of lead is found in their bodies after death, perhaps not more than a few grains in the internal organs after they have been subjected to the most complete and exhaustive examination.

NEW ENGLAND.

— The executors of the will of the late Dr. T. J. W. Pray of Dover, N. H., have recently paid a legacy of \$1,000 in his will to Dr. L. G. Hill and others as trustees of the New Hampshire Medical Society.

NEW YORK.

— Mr. Cornelius Vanderbilt, in conjunction with his mother, Mrs. Wm. H. Vanderbilt, has given \$250,000 for the erection and maintenance of a building on East Forty-second Street, to be known as St. Bartholomew's Mission, which is designed for the health and comfort, as well as the morals, of the tenement population in the neighborhood. It will be constructed of white brick with dark red terra-cotta trimmings, and will be six stories high with a depth of one hundred feet and width of seventy-five feet. In the basement there will be a large swimming bath for the use, at different hours, of both sexes, with a heating apparatus for cold weather. On this floor will also be a kitchen and dining-room and a work-room for the temporary employment of people out of work. The main floor will be occupied by the chapel and a large hall for mission services, which will be two stories in height. The third floor will be devoted to rooms for the Sunday school and for mother's meetings and sewing classes; and the fourth to a library, reading-room, boys' club and assembly and class rooms. The fifth floor will be fitted up as a fully equipped gymnasium, to be open at different hours to both men and women, and on the upper floor will be the offices and living rooms of those engaged in the administration of the establishment. The whole is to be under the direction of the rector of St. Bartholomew's church.

— The city's mortuary reports are showing the effect of the recent hot weather. During the week ending July 5th, 1,010 deaths were recorded, an increase of 135 over the previous week, and showing a death-rate of 32.29 in an estimated population of

1,631,848. Of these, 326 were from diarrhoeal diseases in infants and young children. In order to prevent as far as possible the excessive mortality liable to occur among the children of the tenement-house population during the hot weather the usual summer corps of extra physicians has been appointed by the Board of Health, and they have been hard at work in house to house visitation since the first of July. The St. John's Guild Floating Hospital excursions and other charitable agencies for removing poor children temporarily to the country and seaside also have a favorable effect in keeping down the number of deaths.

— In a case in Brooklyn in which a patient was supposed to have died of an over-dose of hyoscyamine, in consequence of a druggist's mistake, the undertaker in charge of the body in some way was allowed to use an embalming process (which effectually destroyed all traces of the poison, if such there were), before the coroner made his post-mortem examination. Consequently the case against the clerk who put up the prescription, who had been held in \$2,000 bail, will probably fall to the ground.

— A druggist's clerk on Centre Street recently made the blunder of giving oxalic acid to a man who asked for five cents' worth of Epsom salt; but fortunately it was discovered that a mistake had been made in time to save the patient's life. He was promptly taken to the Chambers Street Hospital, and the use of the stomach pump was followed by a satisfactory result.

— All preparations have been made for opening the new Croton aqueduct on the 15th of July. The tunnel of the aqueduct is 29.63 miles long, and its estimated capacity is 318,000,000 gallons for twenty-four hours. The pipe line from 135th Street to the reservoirs in Central Park has a capacity of 250,000,000 gallons for twenty-four hours, and is 2.37 miles long.

— The State Commission in Lunacy, as a result of a series of visitations recently made to the State asylums, has urged the adoption of very strict regulations for the prevention of fire in these institutions.

— For the third time Kemmler has been sentenced to death, and the execution is now fixed for the week beginning August 4th, at Auburn Prison.

— The Board of Health has been making an investigation of the pipes of the Steam Heating Company in the lower part of the city, and in consequence of the results brought to light, has passed a resolution to effect that in its opinion the heat from the steam mains that are laid in close proximity to the gas mains, to the Croton water mains and to the sewers and vaults, creates new and dangerous emergencies and greatly increases the risk to the public health from the streets and street openings, sewers and vaults in the part of the city examined; and that the extreme heat coming from these mains is a menace to the public health, and its effect on the basements of many buildings situated along the line of these steam

mains is productive of conditions dangerous and detrimental to life and health. In accordance with this resolution the Board, by virtue of the authority legally vested in it, has issued orders declaring the steam mains at certain points to be a public nuisance, and requiring that they no longer be used.

The investigation showed that the high temperature noted was to be ascribed in part to direct radiation from the steam mains and in part to the escape of steam from leaks in the mains. In some places the water service was affected; the water being delivered at a very high temperature. The report of the inspectors who made the examination goes on to say: "The numerous explosions which have occurred, especially in the lower districts of the city, are chiefly due to leakage of gas from the gas mains, as would appear from the fact that the leakage is greater from the mains laid in streets in which there are steam mains than elsewhere. . . . The heat of the steam mains is intermittent and causes contraction and expansion of the gas mains, thereby loosening the joints and causing them to leak. . . . The gas escapes into sewers and subway manholes, forming an explosive mixture with the air. It becomes ignited and explosion ensues."

Miscellany.

STANLEY'S ESTIMATE OF HIS DOCTOR.

In Stanley's book "In Darkest Africa" he speaks repeatedly with the greatest esteem of the medical officer of the expedition, Surgeon Parke. We insert one such paragraph:

"This expedition possesses the rarest doctor in the world. No country in Europe can produce his equal in my opinion. There may be many more learned perhaps, more skilful, older, or younger, as the case may be, but the best of them have something to learn from our doctor. He is such a combination of sweetness and simplicity; so unostentatious, so genuinely unobtrusive. We are all bound to him with cords of love. We have seen him do so much out of pure love for his 'cases,' that human nature becomes ennobled by this gem. He is tenderness itself. He has saved many lives by his devoted nursing. We see him each day at 8 a. m. and 5 p. m., with his selectest circle of 'sick' around him. None with tender stomach dare approach it. He sits in the centre as though it was a rare perfume. The sloughing ulcers are exposed to view, some fearful to behold, and presenting a spectacle of horror. The doctor smiles and sweetly sniffs the tainted air, handles the swollen limbs, cleanses them from impurity, pours the soothing lotion, cheers the sufferers, binds up the painful wounds, and sends the patient away with a hopeful and grateful look. May the kindly angels record this nobleness and obliterate all else! I greatly honor what is divine in man. This gift of gentleness and exquisite sensibility appeals to the dullest. At Abu-Klea our doctor was great; the wounded had cause to bless him; on the green sward of Kavalli, daily ministering to these suffering blacks, unknowing and unheeding whether any regarded him, our doctor was greater still."

MEDICAL INSPECTION OF IMMIGRANTS BY CONSULAR PHYSICIANS.

PRESS dispatches state that the United States Marine Hospital service has decided to establish physicians at every port in Europe from which immigrants embark to this country, in connection with the United States Marine-Hospital service.

The physicians will, in every case, work under the supervision of the United States Consul at the port where they are stationed. It will be the duty of these doctors to examine immigrants intending to sail for this port, and to prevent the embarkation of the great army of the lame, the halt and the blind people, who for years have been pouring into this country, only to fill up the county and State pauper institutions.

Particular attention will be given to rejecting people suffering from contagious diseases and all complaints of a scrofulous nature.

The plan proposed has been successfully carried out in connection with the Marine-Hospital service in West Indian and South American ports, and the effect of this protection to the United States in the exclusion of contagious diseases is considered incalculable by the members of the service. Thus, while yellow fever is raging at Santos and Rio Janeiro, Brazil, there is very little danger of its getting into New York, even in the summer season.

In connection with this work, the European consuls are expected to also make examinations particularly with regard to criminal cases and those who claim to be citizens of this country. If the candidate proves to be actually a citizen, the consul will issue to him a certificate.

It is understood that women about to become mothers will also be included in the class to be kept from embarking.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 5, 1890.

Cities.	Estimated Population for 1890.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3,405; under five years of age 1,960: principal infectious diseases small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,203, diarrhoeal diseases 265, diphtheria and croup 84, typhoid fever 44, measles 28, whooping-cough 27, scarlet fever 21, malarial fevers 19, cerebro-spinal meningitis 11, erysipelas 4.

From measles, New York 23, Baltimore 3, Brooklyn and Boston 1 each. From whooping-cough, New York 10, Philadelphia 4, Brooklyn, Boston and Cambridge 2 each, St. Louis, Baltimore, Washington, Charleston, Lowell, Lawrence and Quincy 1 each. From scarlet fever, New York 9, Brooklyn 4, Baltimore 3, Philadelphia, Boston, Washington, Worcester and Springfield 1 each. From malarial fever, New Orleans 9, New York 5, Brooklyn 2, Philadelphia, Baltimore and Nashville 1 each. From

cerebro-spinal meningitis, New York 4, Brooklyn, Baltimore, Boston, Washington, Fall River, Lynn and Gloucester 1 each. From erysipelas, New York 3, Brooklyn 1.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,539, for the week ending June 21st, the death-rate was 17.9: deaths reported 3,334: acute diseases of the respiratory organs (London) 215, measles 172, whooping-cough 98, scarlet fever 65, diarrhoea 57, fever 35, diphtheria 32, small-pox (Derby and Hull 1 each) 2.

The death-rates ranged from 11.8 in Brighton to 29.0 in Manchester: Birmingham 18.6, Bolton 23.9, Hull 15.9, Leeds 14.9, Leicester 14.9, Liverpool 21.3, London 16.4, Nottingham 12.6, Sheffield 24.4.

In Edinburgh 16.9, Glasgow 25.9, Dublin 20.8.

The meteorological record for the week ending July 5, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:-

Week ending	Barometer.		Thermometer.		Relative Humidity.		Direction of Wind.		Velocity of Wind.		State of Weather.*		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 4, 1890, TO JULY 11, 1890.

Captain JOHN DE B. W. GARDINER, assistant surgeon, having been found incapacitated for active service by an army retiring board, and having complied with paragraph 12, Special Orders 35, June 10, 1890, from this office, is, by direction of the acting Secretary of War, granted leave of absence until further orders on account of disability. Par. 3, S. O. 153, A. G. O., July 2, 1890, Washington, D. C.

By direction of the Secretary of War, the leave of absence, on surgeon's certificate, granted Captain MARCUS E. TAYLOR, assistant surgeon in Special Orders 45, June 13, 1890, division of the Pacific, is extended five months on surgeon's certificate of disability, with permission to go beyond sea. Par. 6, S. O. 159, A. G. O., July 10, 1890.

Captain SAMUEL Q. ROBINSON, assistant surgeon, is relieved from temporary duty in the United States Medical Academy, West Point, N. Y., to take effect upon the arrival there of Captain W. Fitzhugh Carter, assistant surgeon, and will report in person to the commanding officer, Fort Du Chesne, Utah, Ty., for duty, relieving Captain Curtis E. Price, assistant surgeon. Captain PRICE, on being relieved by Captain Robinson, will proceed to Fort Wardsworth, New York Harbor, and report in person to the commanding officer of that post for duty, relieving Captain Robert B. Benham, assistant surgeon. Captain BENHAM, on being thus relieved from temporary duty at Fort Wardsworth, will report in person, without delay, to the commanding officer, Fort Hamilton, New York Harbor, for duty. Par. 12, S. O. 153, A. G. O., July 2, 1890, Washington, D. C.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 12, 1890.

RIXEY, P. H., surgeon, leave of absence granted for fifteen days.

ODGEN, F. N., assistant surgeon, promoted to be a passed assistant surgeon.

WHITE, S. STUART, assistant surgeon, promoted to be a passed assistant surgeon.

ATLEE, L. W., assistant surgeon, granted three months' leave of absence.

WOOLVERTON, T., medical inspector, await orders to the U. S. S. "Philadelphia."

LOVERING, P. A., past assistant surgeon, await orders to the U. S. S. "Philadelphia."

MCMURTHIE, D., medical inspector, granted leave of absence for thirty days.

OBITUARY. WILLARD EVERETT SMITH, M.D., M.M.S.S.

Dr. Willard Everett Smith died, at his home in Boston, July 14th, after an eight days' illness from peritonitis. Dr. Smith was a graduate of the Harvard Medical School in 1882. He first located for practice in Framingham Centre, marrying his wife, a Miss Newell, there. A few years ago he removed to Boston. He had been a valued contributor to this JOURNAL, and had prepared useful reports to the Massachusetts Medical Society on the Distribution of Disease in this State.

I, II, III, IV, V. Philadelphia, New York, Chicago, Atlanta and London: F. A. Davis. 1890.

Lecture.**INFLUENZA IN MASSACHUSETTS.¹**

BY GEORGE B. SHATTUCK, M.D., OF BOSTON.

BRISTOL COUNTY.

I HAVE tabulated thirteen manufacturers' returns from Bristol County, covering about 7,000 employees. Of these three are from New Bedford, six from Fall River, three from Taunton — all in the southern half of the county — and one from Attleboro near the northern border.

The earliest first case, December 14th, is reported from Attleboro' at the north, but two mills at Fall River report first cases December 15th; the latest first cases are at Fall River and New Bedford — the southern extremity, but in close railroad communication with Boston — each January 6th; the largest mill at New Bedford, however, reports its first case December 31st, and the third mill January 1st.

The three returns from Taunton agree substantially upon December 30th as the date of the first case. All the returns, except one from Fall River, which names the last week of December, agree practically upon the second week of January as the maximum week.

The percentage of affected varies from 60% to 5%, the average being 29%; the absence from work an average of five days.

The superintendent of the Granite Cotton Mill at Fall River writes a letter of some interest under date of February 4th:

"The influenza made its appearance among our people December 27th, the day after the great gale which swept over the Eastern States. December 30th, when the temperature fell from 54° F. to 37° F., the number of victims increased rapidly, and reached a crisis a few days after January 1st, when there was another fall in temperature from 36° to 20°, followed by a cold wave, which those who dressed in holiday attire and engaged in New Year's festivities were not prepared to meet, and the number of victims continued to increase until January 13th, when a large percentage returned to work, and since that the number of those off work has steadily decreased, and to-day there are only seven cases among 836 employees.

The treasurer of a cotton mill at Taunton, 1,200 employees, sends very accurate figures, from which it appears that of 650 males, 221 were sick, an average of 4.73 days; and of 550 females, 259 were sick, an average of 5.95; so that at this mill the females were sick in greater numbers and more seriously.

Medical Returns. — I have tabulated seven medical returns from this county, all from the southern half of the county, except one from Attleboro'. The earliest first case is December 10th, from New Bedford; the latest first case, December 28th, from Fall River near by. The next earliest case is from Attleboro', at the northern part of the county, December 18th. All the returns, except one, which gives the first week in January, name the second week in January as the maximum week.

The percentage of affected varies from 60% in Attleboro' to 10% in Fall River. Average 33%.

¹ Delivered before the Massachusetts Medical Society June 10, 1890. Continued from page 52 of the Journal.

Sex. — Three state that males were most affected, one females.

Other Diseases. — Four returns state that pneumonia was most increased in frequency.

Conclusions. — I think we may conclude from the two classes of returns in this county that influenza was at least a week later here than in Boston (Suffolk County) and that where males and females were equally withdrawn from out-door exposure the females suffered more.

PLYMOUTH COUNTY.

Only three factory returns received, all three from shoe shops in Brockton and its neighbor Campello, in the northwestern corner of the county. These returns cover nearly 1,000 employees.

The answers to question 1 are January 1st, 2d and 10th; to question 2, the 3d of January, the second week and the third week; that the climax was not reached any earlier in the shop where the first case occurred January 1st, than where it occurred January 10th. The percentages of affected were 60%, 20%, and 40%; and the days of absence from work 2, 7 and 5. The sexes are returned as affected alike.

Medical Returns. — There are four from Plymouth County. From Abington the answers to questions 1 and 2 are December 5th and the week from December 29th to January 4th; from Brockton the answers to 1 and 2 are December 20th and second week in January; to question 3 this return gives 50% of the population as attacked. From Middleboro', farther south, the first case is reported as occurring on the same day as at Brockton, and the climax as occurring the same week, but only 10% of the population was affected.

From Rockland, the next township to Abington, the first case is set down for December 22d, eighteen days later than the first case at Abington; the climax, however, was reached about the same time in the two towns; at Rockland only 6% is returned as attacked.

Three of the four answer the male sex to question 5; two specify pneumonia, and one pulmonary disease as being increased.

Obviously no definite conclusions can be drawn from the returns from this county.

The case in Abington, December 4th, was probably antecedent to the true epidemic; and the epidemic perhaps began a little later and culminated a little later than in Suffolk County.

NORFOLK COUNTY.

Five factory returns, one silk, one woollen, one cotton, one straw, cover from 1,500 to 2,000 employees. The earliest first case is December 16th, the latest December 28th; in two returns the climax is reached the first week in January, in two the second week in January, in one the week January 4th to 11th.

The silk factory reports 60% of affected and of absentees an average of 5 days; the straw factory 50% of affected and 20% of absentees, an average of 3 days; the woollen mill 15% of affected and 10% of absentees, an average of 4 days; the cotton mill 6% of affected and 3% of absentees, an average of 3 days. The first case at the woollen mill in Dedham was December 16th, and the first case at the cotton mill at Readville in the next township was December 25th, but the period of greatest activity at each was the first week in January.

Medical Returns.—There are thirteen from Norfolk County representing twelve different towns. West Medway, at the western border of the county, reports a first case as early as October 20th—evidently a sporadic case of catarrhal fever; Hingham near the coast, and just north of Abington, with its first case December 4th, reports its first case November 15th; 12 "distinct cases" are reported as occurring in Brookline November 17th—perhaps a local outbreak; Stoughton, on the southern border of the county and contiguous to Brockton, with its first case December 20th, reports a first case November 20th; Dedham's first case is returned for December 12th; of two returns from Hyde Park, one gives the first case as December 7th, the other December 27th; the Medical Examiner at Brookline gives the date of the first case there as December 15th; the first case at Foxboro' is the latest—December 25th. East Weymouth gives December 21st; Braintree and Randolph (next to Stoughton with its first case November 20th) give December 20th. Eight towns return the first week in January or the week from December 28th to January 4th, as the week of greatest prevalence. Two towns, West Medway with its first case October 20th, and Hingham with a first case November 15th, report the second week of January as the week of greatest prevalence, which indicates pretty well the character of the so-called first cases. The return from Hyde Park which dates the first case December 7th, puts the climax at the fourth week of December; that from Quincy which dates the first case December 1st, puts the climax the first week in January, the same week as those dating the first case December 20th. At Braintree and Wellesley Hills 75% of the population is said to have been attacked; various percentages are given for the other towns between this and 20% for Hingham and 15% for Brookline at the other end of the scale. The average is 51%.

Sex.—Eight returns from as many different towns specify the male sex as having been most severely affected. The others make no return to this question, except one which states that the female population was the larger.

Medical Returns.—Seven returns state that pneumonia was increased, and three others that pulmonary diseases were increased. One return mentions capillary bronchitis in connection with pneumonia.

SUFFOLK COUNTY,

the next on the north, is really the City of Boston with Chelsea; from the small towns of Revere and Winthrop, also within the county limits, there are no returns.

There are seven returns from the large Boston dry goods stores. One places the first case as early as December 1st, but reports the same week of greatest prevalence (December 28th to January 4th) as another store which reports the latest first case of the seven, December 22d. Two date the first case December 10th, one December 16th, one the 20th. Four give Christmas week as the climax, but this is partially explained by one return which says: "Our employees were lightly touched, and there were no more absences than usual at Christmas time which is always the cause of much fatigue." Two stores return 50% of employees as affected and 45% as absent in consequence; one returns 50% as affected but only 5% as absent—a singular discrepancy; one,

33% as affected and 25% absent; one, 10% affected and absent. The average duration of absence varied from 2 to 7 days. Two stores report the male sex as most seriously affected.

There are returns from nine banks and Trust Companies. Among the personnel of two banks no case of influenza occurred. One dates the first case December 10th, one December 13th, one December 16th, one December 17th, one December 20th and one the 27th. The large banking house with 44 employees reporting its first case December 13th, gives the second week of December as the week of greatest prevalence; 60% were attacked and 45% were absent an average of four days. If this is a correct statement, and there is every reason to accept it, it indicates that the epidemic exhibited an almost explosive character at this point.

A Trust Company, with 26 officers and clerks, dating its first case December 17th, gives the immediately following week as that of greatest prevalence.

Two banks report 75% of affected with 25% and 20% of absentees; one, 50% with 33% absent; one, 33% affected and absent; one, 25% affected and absent. The average of absences varied from three to six days.

At the Trust Company with 26 employees, three had a second attack incapacitating for work; and "the oldest" of the staff are reported to have had immunity.

These bank returns dealing with comparatively small numbers under immediate supervision, are probably pretty reliable. They indicate that the influenza began as an epidemic in Boston about the middle of December and was on the wane by January 4th; that at least 50% of the young and middle-aged male population were attacked, and that about 25% were incapacitated for work for four or five days.

The return of the Central Boston Post Office where there are 472 employees (clerks), dates the first case December 15th, and the week of greatest prevalence December 28th to January 4th, which corresponds pretty accurately with the hospital and medical returns; 29% were said to be affected, 22% were incapacitated and absent an average of four days; male employees were most severely affected, but only 25 women are employed.

The North End Station of the Boston Gas Light Company employs 320 men, and dates its first case December 27th, and its week of climax is given as the first week in January; 55% were attacked and 18% absent an average of three days. The Superintendent writes a somewhat interesting letter, to the following effect:

"At the South Boston works, where thirty men were employed, the first case appeared December 28th, and it prevailed unceasingly the first three weeks in January; 64% of all men were attacked, and all were obliged to leave work about four days. The last case was cured January 24th. Men who worked at the fires and were subjected to heat and chill, and men of sedentary habits were attacked. Every man in the

* In response to my request, separate returns were made up for the telephone clerks, 153 in number, at the Central Station, who were mainly men working in the open air, thus differing from the office workers. The week ending December 10th, a daily average of 6.3% were absent from duty, December 19th, 6.14%; December 27th, 6.6%; January 4th, 10.36%; January 12th, 11.67%; January 22d, 9.48%; January 30th, 10.4%; February 8th, 10.44%. The percentage of daily absences was doubled from the week ending December 10th to that ending January 12th. The maximum week was apparently a week later than among the clerks.

retort houses and all the office men had it, while only one street laborer, and none of the yard men were attacked."

The Whittier Machine Company of the Roxbury District, employing 261 men, presents a singular return; its first case was December 22d, the week of climax the first in January, only 4½% were attacked and only 2½% absent an average of seven days. The Chelsea Dye House had its first case December 5th, its maximum week the fourth week in December, 40% of its 92 employees were attacked and 35% absent an average of seven days.

The average percentage of affected in eight mercantile houses in Boston, employing males, almost exclusively, is 50%.

Medical Returns. — There are twenty-three from Suffolk County — all from Boston except one from Chelsea — which I have tabulated.

One first case is reported December 1st, one December 5th, three December 12th, but in each of these returns the maximum week is given as the last week in December. The Chelsea return dates the first case as late as December 25th and the maximum week the first week of January.

The latest first cases returned from Boston proper are those dated December 20th. The greatest number of returns (five) giving the same date for the first case are for December 17th, and there are three giving December 16th. It would be fair to assume the middle of December as the date of the beginning of the epidemic in Boston. Ten returns give the last week of December as the maximum week, three the week from December 28th to January 4th, and three the first week of January. It is probably fair to assume that the epidemic began to decline in Boston about the end of the first week of January.

It took, therefore, ten or twelve days to reach its climax, where it held probably five or six days.

One return from Charlestown District gives 80% as the proportion of the population attacked, one from Brighton 75%, one from Roxbury 70%, two from Boston proper 65%, two 50% — these must be estimates or guesses. One return says 44% of persons in families visited, one 25% in families visited. The lowest percentage from Boston proper is 20%, and the lowest of all, from Chelsea, 17%. The average is 44%.

Sex. — Of those answering question No. 5 as to sex, five say male, three female, one "happened to be female in my practice."

Other Diseases. — Twenty-three state that pneumonia was increased (one specifying fibrinous pneumonia); one states that pulmonary diseases were increased; one mentions gastritis; only one specifies insomnia as a complication. In the practice of one there was a general immunity from other diseases during the latter part of the epidemic. The mention of bronchitis is so usual in all these returns that I omit it.

As to the question of sex or exposure in the open air, two correlated factors as it seems to me elsewhere, it is difficult to draw any definite conclusions from the medical returns of Suffolk; but it is pretty evident that pneumonia was increased.

ESSEX COUNTY.

Extending along the coast and immediately to the north of Suffolk, I take up Essex County next.

I have tabulated 16 returns from manufacturing companies, etc., in this county, and 21 medical returns from 14 different towns.

A Lynn shoe shop (the only one reporting on account of the fire), with 210 employees, reports its first case January 1st, and its maximum week the second in January; the first case at the Lynn Bank was December 28th.

From Beverly, two shoe shops, each employing about 300 men, report. One says its first case was "about November," its maximum week the second of December, 90% of the employees were affected and 75% were absent an average of ten days. The other reports its first case December 20th, its maximum January 1st, 50% were attacked and absent an average of four days. These shops are very near each other, and it is impossible to reconcile the two statements unless we explain the first by a "strike" rather than by influenza.

From Salem, a Bank reports its first case December 21st; five out of six were affected; but the Naumkeag Cotton Mills of Salem, with 1,078 employees, reports the first case "about January 1st," the maximum week January 4th to 11th, 40% attacked, 13% absent an average of five days. The Ipswich Cotton Mills, 522 hands, same date for the first case, January 11th to 18th for the maximum. Two mills at Newburyport, employing together 580 hands, report first cases January 3d and 4th, maximum weeks January 4th to 11th and the second week of January, 25% and 43% of affected and absent an average of seven days.

A Haverhill shoe shop, with 400 employees, reports its first case December 20th, its maximum week December 28th to January 4th, 75% affected, 25% absent. From Lawrence there are two returns. Of the Great Pacific Mills, with 4,336 employees, very full, accurate and reliable returns may be found in the *Boston Medical and Surgical Journal*, Vol. CXXII, p. 251, to which reference will be made later.

The first case at the Pacific Mills occurred December 24th, the maximum week was January 4th to 11th, 40% were affected and absent an average of 6½ days, females were the most and the more seriously affected.

The Pemberton Cotton Mills of Lawrence, with 676 employees, report the first case December 17th, the maximum week January 4th to 11th, 41% were affected (lost time in consequence) and out an average of 5½ days; females were most attacked, 49% of the females and only 29% of the males. The report from this mill is also apparently accurate and reliable, and agrees in the main with the Pacific report.

A linen mill at Andover, 308 employees, reports first case December 14th, maximum week second week of January, 41% attacked, 38% out. A machine shop at North Andover, 421 hands, all males, December 25th, January 5th to 12th, 40% attacked and out five days.

Medical Returns. — One return from a coast town (Newburyport) and one from an interior town (North Andover) date the first case December 1st; but the return from Andover, next to North Andover, dates the first case December 21st, and gives the maximum week as the second week of January, and the other return from Newburyport names January 1st to 15th as the maximum period, so that these early cases may be considered sporadic, as similar ones have been in other counties.

The latest returns of first cases are from Marblehead

and Manchester on the coast and Methuen in the interior, all January 1st; the maximum week at Methuen is given as the third in January, at Manchester, January 5th to 11th.

Lynn returns December 15th; Peabody, December 10th, with a maximum in the second week in January; Danvers, one return December 15th, one December 25th, with the third and second weeks of January as maximum weeks respectively; Gloucester, December 18th and 24th, both returns naming January 5th to 11th as a maximum week; Haverhill, December 20th and 28th, with the first and second weeks of January respectively as maximum weeks.

West Newburyport next to Newburyport, gives December 16th as the date of the first case.

Lawrence, December 20th, 21st and 23d, with the first week of January as a maximum week for the first two, and January 7th to 21st for the third return.

Georgetown, in the northwestern corner of the county, gives December 16th as the date of its first case, and the middle of January as the maximum period.

The percentages of population attacked range from 80% in Marblehead to 5% from one return from Haverhill, the other return from Haverhill, giving 23%. One return from Danvers give 60%, the other 10%; one return from Lawrence gives 50%, one 25% and one 12%. The return from Andover says 50%, that from North Andover 15%. The average of twenty returns 38%.

Sex. — Eleven returns specify the male sex in answer to question 5; three returns say females, but in one of these the practice is among females.

Other Diseases. — Eleven returns state that pneumonia was increased, three specify catarrhal and one croupous pneumonia. Four state that pulmonary diseases were increased. Two mention gastro-intestinal disorders as complications. A medical examiner reports two deaths without treatment, "probably from congestive pneumonia." One return from Lawrence states that influenza "drove out" diphtheria which had been prevalent.

MIDDLESEX COUNTY.

This county, lying next to Essex and Suffolk, brings us back from the northern border of the State to the neighborhood of Boston. It is almost wholly an interior county, and, except for a small though thickly-populated territory around Boston, we take leave of the immediate influence of the sea. It is a manufacturing population. I have tabulated 27 returns from factories, banks, machine shops, etc.

From Lowell, in the northern part of the county, seven returns cover nearly 9,000 employees. The Lowell Cotton Mills, with 1,736 employees, report the earliest first case December 20th, with a maximum week the same as that in Boston, namely, December 28th to January 4th. The Merrimac Woollen Mills report the latest first case January 10th, with a maximum week the second week of January; there are three first cases December 26th; one, December 30th; two, January 1st; four mills give the second week of January as the maximum week, two mills January 4th to 11th, one and the Bank (only five employees) December 28th to January 4th.

The percentages of the affected and absent, at the mills in Lowell, varied very much, according to these returns, from "nearly every one" affected, and 50% absent an average of four days at the Merrimac Cotton

Mills and Print Works, to 10% affected and 8% absent an average of four days at the Merrimac Woollen Mills. The favorable return, if accurate, from the Merrimac Woollen Mills was probably due to something other than wool, for the Middlesex Woollen Mills report 50% affected and 20% absent an average of five days.

The different departments of the same mills were as differently affected as the different mills. To this point I shall revert again later. Five days was about the average of absence from work.

Sex. — As far as the Lowell returns offer any reliable information upon that point, the female sex was the most affected. Careful calculations from the Merrimac Cotton, with 3,200 employees, in answer to a special request, show that influenza "was more prevalent among women and boys than among men."

The Pepperell Cotton Mills, 316 employees, in the northwestern corner of the county and somewhat off the main line of travel, though with railroad connection, report the first case January 9th, and the maximum week the third week of January.

The North Billerica Cotton Mills, nearer Boston than Lowell and on the main line of travel, with 265 employees, report the first case "about January 1st," and the maximum week the third week in January. Next to the south, a tannery at South Woburn, 180 employees, has its first case October 4th, its maximum week the second week in October, 6% attacked and 5% absent an average of thirteen days — evidently a local predecessor of the great epidemic for a Winchester factory a few miles away and still nearer Boston, reports its first case December 26th, its maximum week the first week of January. The Malden Rubber Shoe Company, 1,255 employees, with dates agreeing pretty closely with those previously recorded in Suffolk County, had only 15% attacked and 12% absent an average of five days. The returns from manufacturers in Cambridge, Watertown, Waltham, Newton, covering 4,200 employees, vary but little from those given for Suffolk County, but the first cases are a few days later and the maximum weeks a few days later. The Nonantum Worsted Company at Newton, 520 employees, reports its first case December 30th, its maximum week January 4th to 11th, 17% of affected and absent an average of five days.

The Waltham Watch Works, 2,300 employees, reports males as most affected. Returns from two shoe shops at Marlborough, 1,100 employees, report first cases December 22d and 26th, and the maximum week the first week of January and January 4th to 11th; from woolen mills at Maynard, 886 employees, the first case was December 20th, and the maximum week January 4th to 11th; Marlborough and Maynard are in the western part of the Middlesex near the Worcester line.

Medical Returns. — I have tabulated 26 medical returns from this county. Beginning again with Lowell, near the northern line, there are two returns, one placing the first case December 10th, and the maximum week the second week of January; the other, December 21st. Billerica returns the first case December 12th, and the maximum week the second week of January; from Ayer in the northwest, near the Worcester County line, the medical examiner of the district, Dr. Hartwell, returns the first case as December 21st, and the maximum week the second week in January. He writes: "I go into four or five

adjoining towns. Ayer is a large railroad centre. The epidemic began here and reached its height from one to two weeks earlier than in places off the line of travel, and, as far as my observation goes, affected a larger number of the inhabitants.

"The only case I saw as medical examiner was one in Pepperell, said by the neighbors and thought by selectmen to have died from influenza, but proved, on examination, to have died of acute alcoholism."

Returns from towns around Boston — Somerville, Medford, Melrose, Arlington, Cambridge, Waltham, Lexington, Concord, Newtonville, Newton — though varying considerably in the dates of first cases, and still more so in different returns for the same towns (Cambridge, for instance, returning November 15th, 24th, December 1st, 23d, as dates of the first case), agree on the average with the Boston returns, as do those also of the date of the maximum week. Returns from Framingham and Hopkinton, in the southwestern corner of the county, agree as to dates with those from Boston.

The percentage of the affected varies from 75% in five returns to 10% in two returns. It also varies within these same limits for different returns from the same place. The return of the medical examiner, resident at Somerville, estimated 75% of the population attacked; another return from Somerville names 10% as proportion. The average percentage of twenty-four returns tabulated is 44%.

Sex. — Fifteen returns specify the male sex as suffering either most numerously or most severely. Of these, one reads: "Males who were most exposed to weather and hard work"; one return says: "In numbers, females suffered more; in severity, sexes alike"; one return says: "More cases among females, more complications among males"; one return says: "Females more frequently attacked, in the proportion of 3:2.

Other Diseases. — Eleven returns state that pneumonia was increased, and eight that pulmonary diseases were increased; one return states that there was less pneumonia than usual; one reply, affirming an increase of pneumonia, expresses doubt whether "the pneumonia had any direct connection with the influenza, or whether it was an independent disease attacking those already debilitated"; and another reply is accompanied by this comment: "Most cases of so-called pneumonia following influenza are in reality cases of congestion, not croupous pneumonia." Another return states: "No diarrhoea, no constipation, no diseases increased in frequency or severity."

A member of the Board of Health of Lowell writes: "Scarlet fever, which had been rapidly increasing for four weeks, with the first week in January (the maximum week of influenza), suddenly decreased, and the same is true of diphtheria, though in a less degree." This coincides with a return from Lawrence previously alluded to.

(To be continued.)

— The *Medical Record* says that seventeen fatal cases of poisoning from antipyrine occurred in one week in Vienna during the prevalence of the influenza. In many of these cases the drug was bought by the victims themselves without a physician's prescription; but, partly in consequence of these fatalities, it is now illegal to sell antipyrene except upon a written prescription from a physician.

COLLES' FRACTURE WITH ESPECIAL REFERENCE TO TREATMENT.¹

BY E. C. HUSE, M.D., GEORGETOWN, MASS.

At the risk of being accused of pedantry, I invite your attention to the above subject, hoping in the course of the discussion of the topic to elicit some new facts from my brethren, while at the same time contributing my experience in a number of cases occurring in twenty-four years of country practice.

With one exception, the clavicle, no bone is more frequently fractured than the lower end of the radius; according to Stimson, occurring more frequently in elderly women. Mentioned first by Poteau about the year 1783, it failed to attract much notice until 1814, when Richard Colles succinctly and accurately described it, and with that degree of success that the title "Colles' fracture" has come down to us as a distinctive appellation, and serves as a monument to mark the wisdom and the genius of a great man.

Probably the difficulty of thoroughly understanding the pathological condition of the parts arises from infrequent opportunities for dissection. I may here remark that Professor Morton, of Philadelphia, has, since this was written, January, 1890, dissected and reported a typical case, in which the lower fragment with the hand was to be plainly seen overriding the upper extremity.

Certainly the fact exists that in times past many cases have been considered dislocations of the wrist, and, in consequence thereof, have been subjected to severe and unnecessary force for the reduction of the same, to the great detriment of the tendons and the large nerve trunks lying in close relation to the broken ends, the result being a far worse condition of affairs if left alone, and in the same unreduced condition they were actually and finally left.

Even as late as the year 1821, Sir Astley Cooper, one of our great surgical lights, evidently confounded it with dislocation of the wrist, and thought that powerful extension would restore the parts to their normal condition; and not until 1830 did Dupuytren assert and maintain the fact of the existence of such a fracture, both evidently unaware of the discovery of Colles.

Early in professional life, I chanced to see a marked case of Colles' fracture entirely unrecognized and consequently left unreduced, incurring great misfortune to the patient and no little discredit to a valued member of "Essex North." Not many years after, another worthy member was severely maimed in damages for the same sin. These to me, then quite young, were of the nature of night-riding incubi and full of warning. Added to these are the unfortunate results in three cases of my own; the whole serving as a stimulus to inquire as to the factors entering into success or the converse.

Rarely, does the average doctor nowadays make a faulty diagnosis, the surgical landmarks being so well established that the fairly booked man has no trouble in making his diagnosis at a glance. The cause is almost universally conceded to be a fall upon the hand, causing extension or hyperextension. The weight and momentum of the body being suddenly thrown upon the ball of the thumb, which is firmly

¹ Read before the Essex North District Medical Society.

articulated with the trapezium and this in turn with the scaphoid bone which forms the chief part of the radio-carpal joint, transmits the whole force to the radius. Now a glance at the anatomy shows that the radius alone enters into the articulation and a still closer view shows that the bone is not in its entirety perpendicular to the blow, which, therefore, renders it less able to resist with integrity to its structure. The combined forces of the blow being transmitted at an angle to its perpendicular gives a cross strain which divulses, so to speak, the head from the shaft. The pronator quadratus being thus unopposed and probably injured by the fragments tends to draw the shaft toward the "flexors" and laterally toward the ulna, allowing the lower fragment to ride upon the upper, hence the resemblance to a "silver fork." Now the ulna is about the same length as its fellow, the radius, and, while the latter is shortened by overriding or displacement, itself is forced out laterally and downward by the force and weight of the body, causing the characteristic deformity on the ulnar side; and if the anterior and posterior radio-ulnar ligaments are separated, then the escape of the bone from its articulation with the radius is still more marked.

With these causes entering into a typical case of Colles' fracture, it may well give the practitioner opportunity for study and occasion for solicitude as to its outcome. With a case well diagnosed, treatment is, of course, the immediate sequence, and that has many and varied authorities. Stimson, as well as others, considers that in this fracture especially thorough reduction is essential to success.

This might equally well be said of all fractures. But there seems in times past, if not in the present, to have been many obstacles in the way, judging from results in cases seen by the writer. One of the greatest hindrances to the reduction of the parts is their extreme hyperesthesia; in fact, pain is one of the most constant factors in making the diagnosis. This renders the muscular spasm almost irresistible, and to my mind goes far towards making up the frequent diagnosis of impaction. At any rate, it is a fruitful source of the violent extension and rough usage to which many wrists are submitted, and which are so deprecated by all authorities.

To avoid these causes, fruitful of disaster alike to doctor and patient, anesthesia is of the greatest advantage. To speak from experience, my worst results were, in every case, put up without; two of them, however, apparently being so little displaced that I deemed it quite possible to restore them *in situ* without the use of ether. These cases were all in females, which are, according to one authority at least, the most prone to bad results. Given then, a fracture of the wrist, presumably of the radius, *ergo* a Colles', the *sine qua non* is complete anesthesia. After that is accomplished, it is surprising to see how a supposed impaction turns out to be muscular spasm; and where before the strongest kind of extension failed, now the weight of the hand almost suffices to restore the parts to position. And I know that in one case, merely grasping the hand as in hand-shake, the extension not being noticeable, served to perfectly set the bones and they remained fixed. Finally, if the radius is left shortened, or in other words, left unreduced, just so much is the ulna longer, and the hand is drawn back to the radial side, leaving the styloid process of the ulna out of line with the side of the hand, so that it

is not so much a dislocation of the ulna, as of the hand towards the radial side of the arm, away from the ulnar.

As to the retention of the fracture many authors have sought out many devices, each one striving to carry out in his splint, the principle which avoids the characteristic deformity. Perhaps the most familiar are Boud's and Dupuytren's, both of which tend to draw the hand to the ulnar side with a view that in so doing the tendency of the ulna to protrude would be avoided, at the same time keeping up extension on the radial side, which was necessary, in their opinion, to counteract overriding. Other splints looking more at the anatomical shape of the radius, as Carr's and Lewis', have, in later years, received favor at the hand of the profession; the former, Carr's, is probably the development of the shingle and piece of broomstick. Carr seems to have seen the need of support to the upper part of the radius which curves to quite a degree, and which in the ordinary flat splint is left quite unsupported, however well it may be padded. It is well-known and is much in use at the present time, it retains the parts well, but requires pretty frequent supervision; it has done much, however, towards lessening the number of deformities.

Within a few years, Dr. Lewis, of Philadelphia, has offered to the profession an anatomical, metallic splint, perforated with many holes, these perforations opening from within outward, serving to retain the bandages and at the same time contributing to lightness. When lined with a layer of wadding, or two or three thicknesses of old muslin, they are wonderfully comfortable, and from their conformity to the shape of the limb, they give the doctor and the patient more of a feeling of security than any other contrivance. This is no small item when one lives at a great distance from the patient, as the writer can speak from experience in a case happening last winter.

If, then, the fracture is well reduced there are several splints that may be of service, but to the writer the Lewis is of great value for reasons before mentioned. Freedom of the fingers is insisted on by many writers. This seems to me to depend upon the ability of each patient to move them, varying according to the amount of inflammation incident to each injury. The Lewis certainly allows as much of this as any, and, if support for the fingers is needed, this splint is extremely grateful. The amount of the time essential to union is about thirty days; in one case of my own, however, shortening and marked deformity began about the fifth week, going to the extent beyond the original displacement; whether it was not reduced, as before hinted, or from absorption, is an open question.

Since finishing this article, I have visited my two last cases, and find that consolidation was not complete at the end of five weeks in one, as evidenced by the gradual shortening of the radius and a consequent extension of the ulnar. This was one of the cases which was unsatisfactory, being reduced without ether. The other case occurring at the same time in a female of sixty-two, with far greater displacement, is as fine a result as one could desire. This was reduced with ether.

Within a short time, I have seen another case which I had the good fortune to see at the first, but did not reduce, it having been attended by one of the oldest members of "Essex North." I suggested

at the time, as he was quite muscular and there was much displacement, that he should not have it set without ether, but his surgeon said there was no call for it.

This was three years ago. These is now protrusion of the ulna, great weakness of the wrist, with much difficulty of pronation; the most of which, I venture to say, would have been avoided, had reduction under ether been attempted. According to the patient's statement, much violence was used, while only partial success was obtained, as the result shows.

RÉSUMÉ.

Colles' fracture is a dislocation of the head of the radius from its shaft.

The deformity arises from the overlapping of the fragments, the consequent shortening of the radius and the dislocation of the ulna from its fellowship with the radius. Complete reduction is the only cure against deformity. This is much more easily accomplished and far better results are obtained with anesthesia.

Many cases are considered to be impaction simply because of extreme muscular contraction, and consequently left unreduced where complete anesthesia would clear up the whole matter and bring about satisfactory results.

A CASE OF MALIGNANT ENDOCARDITIS SECONDARY TO COLITIS: REMARKS.¹

BY FREDERICK C. SHATTUCK, M.D.,
Jackson Professor of Clinical Medicine, Harvard University; Visiting Physician to the Massachusetts General Hospital, etc.

A MAN, thirty-four years old, a cook, of good family and previous history, was admitted to my ward December 5, 1889. Four weeks before entrance, without known exciting cause, his bowels became loose, moving sometimes eight or nine times daily without pain or tenesmus. A small amount of blood was noticed on the toilet paper, and at the end of a week he first inspected the dejections. He then found that he was passing at times fresh blood without clots, the maximum amount of blood being estimated by him at six ounces. The frequency and character of the discharges remained about the same until a few days before entrance, when they became less frequent and less bloody. The day of entrance he passed, for the first time since the onset of the intestinal affection, a semi-solid motion. He remained at his work until ten days before entrance, when pain, swelling and tenderness in the shoulders and right hip came on with malaise, and compelled him to take to his bed.

At entrance to the hospital the pulse was 100, respiration 24, temperature 101.4°. Physical examination of the internal viscera was absolutely negative, except that the first sound of the heart struck me as rather sharp and valvular. The shoulders and the right hip were painful, especially on motion, and tender; the former were somewhat swollen. Under treatment, the articular inflammation gradually subsided, the right ankle, however, becoming involved; the intestinal symptoms also abated, and within ten days the motions became perfectly normal in every respect, remaining so until death.

The heart was carefully examined every day, and on the eighth day after entrance, a faint, soft, systolic

murmur was heard, limited to a small area over the fourth left costal cartilages. Later, this murmur increased somewhat in intensity and in the area over which it was audible, but never became very loud or diffused; it was never as loud at the apex as midway between that point and the base. No cardiac enlargement was detected, and no further murmurs were developed.

December 12th, the seventh day after entrance, the patient called attention to a "boil" on the inner aspect of his right leg, rather nearer the ankle than the knee. This proved, on examination, to be an abscess, somewhat raised above the surface, with but little surrounding inflammation, darkish in color, with undermined edges. Incision was followed by the escape of about two ounces of pus. A similar abscess was found over mid-sternum, and was also opened. The next day another abscess was found over the seventh rib in the left posterior axillary line. Subsequently two more appeared, one on the left leg, the other on the left great toe. The skin over the abscesses sloughed, and the ulcers spread more or less in spite of the most careful dressing. The tissues about the abscess on the right leg, the first to attract attention, underwent rapid necrosis, and it was daily necessary to trim off an edge at least a quarter of an inch wide.

By December 28th, the ulcerated surface completely encircled the leg, but the general condition of the patient was better, the appetite and digestion were good, he read and played cards. The smaller ulcers were healing, and early in January, 1890, were completely cicatrized. The large ulcer also made rapid progress toward recovery, and was nearly closed at the time of death.

Early in January tympanitic distension of the upper abdominal segment first appeared without tenderness and persisted, gradually though very slowly increasing to the end; but the digestion remained good, and large quantities of nourishment were taken without inconvenience almost to the last. The heart grew weaker, a small bed-sore formed over the sacrum, finally vomiting occurred, and became persistent; nutrient enemas were not retained; the dejections were somewhat loose, but normal in color and free from any gross abnormal constituent.

January 14th, at 2 a.m., he died.

Two or three weeks before death, Dr. Henry Jackson, at my request, was kind enough to make culture experiments with both the blood and the contents of one of the abscesses, which was opened at the time and for the purpose. The most approved methods were adopted and carefully carried out, but all the culture experiments were negative.

Summary. — A vigorous man in the prime of life is taken with the symptoms of intestinal ulceration, probably seated in the colon. After two to three weeks, a polyarthritis, apparently rheumatic, appears. The symptoms of the former soon disappear completely, those of the latter subside. Fever, however, persists; a systolic murmur appears and gradually grows more distinct, but is never as loud over the mitral or basic valves as between them; multiple superficial abscesses form and spread for a time with great rapidity, but ultimately heal; tympanitic distension comes on in the region of the transverse colon; death occurs from exhaustion six weeks after entrance to the hospital, ten weeks after the first symptom indicative of disease.

Clinical Diagnosis. — Malignant endocarditis, prob-

¹ Read before the Boston Society for Medical Improvement, April 28, 1890.

ably originating in the colon, causing multiple cutaneous embolism.

Autopsy. — Eighteen hours after death by Dr. Fitz. Head not opened. Several red patches on the skin, the recent ulcerations described above. Abdomen tympanic and distended. The pericardium contained two ounces of clear, yellow fluid. The heart was normal in size, the right side distended with clotted blood. The aortic and pulmonic orifices were sufficient by the hydrostatic test. The mitral and tricuspid orifices admitted respectively two and three finger tips. The aortic crescents in the vicinity of the corpora aurantii were fringed with small vegetations along the line of apposition, to which small red clots were adherent. The mitral leaflets showed a similar fringe. The muscular substance was an opaque red-gray in color. The lungs, pleura, spleen, liver, bladder and small intestine were sufficiently normal. The kidneys were normal in size and shape; the capsule was slightly more adherent than usual; on section the cortex was rather opaque. The transverse colon and sigmoid flexure were both adherent to the abdominal wall and adjacent coils of small intestine by fibrous adhesions, which were separated with difficulty. The entire colon from the hepatic flexure to the rectum showed extensive ulceration of the mucous membrane, leaving trabeculated and polypoid masses of relatively normal membrane. In places the ulcers reached the peritoneal tissue. The transverse colon was considerably dilated, and contained semi-solid faeces.

Pathological Diagnosis. — Acute verrucous endocarditis; chronic ulcerative colitis and pseudo-polyp.

Malignant endocarditis may well be characterized as multiform as regards symptoms. At this we are the less surprised when we consider that in the decided majority of cases it is a secondary or associated condition, rather than an independent disease; and may, consequently, be overshadowed by symptoms and signs referable to other organs and parts. In a certain proportion of cases, any positive diagnosis is impossible during life; in a second category, there may be strong grounds for suspecting this form of endocarditis; in a third class, a diagnosis, nearly as certain as we can ever make, is to be reached. In simple endocarditis the diagnosis rests almost invariably on cardiac signs; in malignant endocarditis these may be absent or ill-defined, and the diagnosis always requires and often rests mainly on symptoms which are either exclusively general, or local, and more or less widely distant from the heart itself. In this case, the multiple infectious embolism was the diagnostic sign. It should be remembered that malignant endocarditis is not infrequently connected with pneumonia; that it may closely simulate acute mania and meningitis — even the cerebro-spinal form of the latter — typhoid fever, even ague, and pyæmia, of which it is to be regarded in some cases as a part or form; that valves already the seat of a benign and more or less ancient inflammation are sometimes secondarily attacked by the malignant process. Of the latter, Dr. Stedman's case is a good example. The case above reported is the fourth in which I have made a positive diagnosis of malignant endocarditis during life, with post-mortem confirmation in three. In one, seen with Dr. Humphrey of Lawrence who had already made the diagnosis, valvular damage had resulted from an old attack of rheumatic fever; the symptoms were distinctive enough and I am morally sure that the diagnosis was correct,

though there was no post-mortem. In another case, the affection was apparently primary. I have seen other fatal cases in which I thought malignant endocarditis probable; in one patient, who recovered, the diagnosis was doubtful as between malignant endocarditis and aberrant typhoid fever. The strongest point in favor of the latter was, to my mind, the fact of recovery. Most writers assert that malignant endocarditis is uniformly fatal, a view to which it does not seem to me wise to yield unquestioned adherence. We are by no means sure that the benign and malignant forms of endocarditis differ in kind; there are, indeed, reasons for thinking that the difference is chiefly one of degree. A pathological distinction cannot be based on the result alone.

The features of this case which appear to me specially noteworthy are the following:

In the first place, the lesson is enforced that, as Dr. Osler suggested, the adjective malignant is more applicable to these cases than is the term ulcerative. The endocardium was nowhere ulcerated in this case, the heart, taken by itself, showing to the naked eye only changes such as might be found in any recent and fairly well-marked case of warty endocarditis.

Secondly, the strict limitation of embolism to cutaneous vessels is remarkable. The autopsy did not reveal the slightest trace of any embolic process in the internal viscera.

Thirdly, the condition of the colon at the autopsy was remarkable, not only as presenting a rare pathological specimen, but also in that all symptoms indicating intestinal disease subsided soon after entrance to the hospital. Later, marked distension of the colon came on, but the movements of the bowels remained natural to the end. I supposed during life that the distension was due in some manner to embolism of the bowels, a supposition which turned out to be incorrect.

Finally, the failure to find bacteria, even in the contents of one of the abscesses, seems worthy of note. A similar want of result of success with the blood of the patient has attended the efforts of most other observers.²

Dr. Stedman's case, which I saw twice through his kindness, offers some points of sharp contrast with mine. The clinical course was that of pyæmia, certainly as far as the temperature went, and the source of the pyæmia was referred to the heart by exclusion. The diagnosis was helped by the existence of old aortic disease and articular symptoms which preceded and accompanied the early stage of the fatal malady. A point of great interest is that these articular symptoms were again preceded by urethritis, and the case might have been classed as one of gonorrhœal synovitis were it not for subsequent developments. Embolism was absent, because no fragments were detached from the aortic valves, and also because the abscess in the heart wall had certainly no free communication with the arterial system. Its exact condition was impossible to determine on account of the preservative fluid used by the undertakers.

In making our diagnosis at the first consultation, we attached some importance to one sign which the autopsy showed to be misleading. A systolic mitral murmur had recently been superadded to the aortic

² Girode (*Comp. Rend. de Soc. de Biol.*, 1889, p. 629) found basilli, which he was able to cultivate, in blood drawn from the arm of a patient with malignant endocarditis a few moments before death.

regurgitant, and we were inclined to think that this, under the circumstances, indicated the probable implication of the mitral valve in a recent endocarditis. The autopsy showed that the mitral valve was intact. The murmur was consequently dynamic. The lesson is thus again enforced that great caution must be exercised in the interpretation of systolic apex murmurs during pyrexia or in conditions of cardiac debility. The former was present at the time of the first consultation, but the heart was acting with perfect regularity and apparently sufficient force, eighty-four beats to the minute. In this case again the chief diagnostic sign was outside of the heart, namely, the irregular rigors. Add to this the presence of an old endocarditis, or rather its remains, and the diagnosis was practically certain.

NOTE. — Since the above case was reported, the writer has seen a number of times, with Dr. Garland of Boston, another well-marked case of fatal malignant endocarditis originating in gonorrhœa.

OBSERVATIONS ON A CASE OF PERITYPHILITIS.¹

BY JOHN HOMANS, 2ND, M.D.

A. B. was a large stout man, of great physical strength and vigorous appetite, who led an exceptionally active and busy life. Some fourteen years before his death he was seized with a violent pain in the right iliac region, accompanied with some diarrhoea and the presence of a small, hard painful swelling situated on a level with, but towards the umbilicus from the right anterior superior spine of ilium. Owing to the extreme deposit of fat on the abdominal walls it was difficult to ascertain the exact size of the tumor which, however, seemed to be about as large as the palm of a boy's hand, with a sharp upper outline, and impressed the observer, Dr. John Homans, as being a sort of cake of inflammatory material. There was little or no fever, the acute pain lasted some five or six days and then gradually subsided, the swelling slowly disappearing as the pain grew less.

From this time on the patient had several attacks, some five or six in number, of the same nature as that just described, save that they grew more severe and that the inflammatory cake increased in size till in the last attack in which I observed him it extended nearly to the umbilicus, and seemed to run under the edge of the floating ribs, the well-defined outline before described no longer existing. Whether this cake persisted in the intervals of the attacks it was impossible to say; but the patient suffered occasionally from diarrhoea which would last a few days, and was always accompanied by pain in the right groin.

During the last few years of the patient's life he met with one or two quite severe accidents, and contracted a specific infection, which, however, troubled him little after the earlier secondary symptoms. His final illness was a most severe attack of jaundice, the discolouration and itching of the skin being extreme, and the mental depression, languor, headache and all the other well-known cholemic discomforts were present in a marked degree. His strength was gradually undermined and he died rather suddenly at last, having been sick about six weeks.

¹ Read before the Boston Society for Medical Improvement, April 28, 1880.

The autopsy (for notes of which I am indebted to Dr. Morris Longstreth of Philadelphia) showed nothing remarkable save the results of the intense cholera till the abdominal cavity was opened.

The omentum was rolled up and adherent to the border of the liver at the fissure of the gall-bladder, on the right side over the region of the caput colli the peritoneum of the anterior abdominal wall was thickened and rough and a portion of the omentum was still adherent, the result of former inflammation. Around the caput colli and ileum were numerous old adhesions and bands, and the appendix was concealed from view by the mass of old inflammatory structures. It did not present any appearances of ulceration or perforation.

Stomach, liver and duodenum removed *en masse*. The latter was drawn up close under the liver, and the tissues surrounding the common bile-duct from beginning to end were greatly increased. They presented themselves as a mass measuring over two inches in cross-section. A considerable portion of this mass was composed of fat and several lymphatic glands held in very dense connective tissue, much firmer than usual in this situation. The opening of the common bile-duct on the surface of the duodenum could be detected by the eye and was not eroded or ulcerated. A probe passed up the common duct entered easily into the hepatic duct and into the liver, but could not be made to enter the cystic duct. The gall-bladder was found in the midst of the adherent omentum and mass of connective tissue described above, and presented itself as a yellowish-white body of less circumference than the little finger one and one-half inches in length, the fundus being about two inches from the border of the liver; on section no fluid ran. Cavity contained perhaps twenty gall-stones, one the size of a small pea, but mostly about the size of head of an old-fashioned brass pin. These were imbedded in a yellowish gelatinous mucus. Probe passed from the gall-bladder towards the cystic duct failed to enter, and dissection showed that the duct was closed and converted into a fibrous cord surrounded by the mass of connective tissue around the common duct. The liver on section presented a pretty uniform appearance save for some slight evidences of fatty degeneration. The interacinar connective tissue was not increased. The portal veins were normal. The other abdominal organs presented nothing remarkable.

In this case, then, there existed for many years about the caput colli a nodule of inflammation which, after irregular periods of torpidity, would suddenly become active, giving rise to the attacks described above, extending its limits with each successive attack, forming adhesions, causing an increase in connective tissue, till finally the structures thus formed by inflammatory action seized upon the gall-bladder and duct and death followed.

It is interesting to consider whether the result of this case would have been different if the operation recommended by Treves had been performed and the appendix removed in the intervals of the attacks.

Against the sanction of Treves's operation in any case, I think there are two strong arguments, the first of which applies with equal force to Tait's procedure of catheterizing the appendix and pressing back the foreign body, if any exist, into the cæcum. These arguments are, first, the difficulty of finding the appen-

dix; second, a doubt whether the mere removal of the appendix will insure cessation of the attacks.

It is by no means an easy thing to find the appendix in a fulminating case, when the adhesions are recent and easily broken down and the anatomical relations of the parts not much disturbed, but in this case, for instance, with the old, tough adhesions masking the site of operation, the surgical procedure would have been more or less blind and the discovery of the appendix almost more a matter of chance than skill, involving an amount of handling and general turning over of the intestines which would have materially affected the chances of recovery. It should be borne in mind also that the appendix is frequently found in abnormal situations by surgeons who are operating during a first attack. Thus it has been found in the median line, or near the umbilicus. I have discovered it at autopsy hanging down in the pelvis, bathed in pus and nearly touching the rectum, and Dr. G. H. Monks, in a recently reported case, removed the appendix from tumor of the scrotum.

It is probable that wherever the appendix was carried by the inflammatory process, there or thereabouts it would remain, and its change of position would be so great that the landmarks would be partially obliterated.

Granting, however, that the appendix has been successfully removed, or its calibre occluded by stitching, as Tait recommends, can a positive assurance of freedom from further attacks be given? This question must, I think, be answered at present in the negative. In Treves's and Tait's cases a sufficient time has not yet elapsed to make them of any value, and the case described above, at first sight a most favorable one for the operation, would most probably not have been materially aided as, judging from the autopsy, the appendix does not seem to have played a major rôle in the causation of the trouble after the first attack. Treves' or any operation would have to be done early to be of any especial advantage and at this time patients would not be apt to present themselves, while after three or four attacks the amount of inflammatory structures would be so great and the innervation of the organs so affected that the mere removal of the appendix would not be sufficient to stop the trouble. If, then, a patient recovers from one or two attacks under medical treatment and then seeks relief during the interval through surgical aid, there is a strong probability that the operator by not finding the appendix in its normal surroundings may subject his patient to an operation dangerous because of its length and the resulting shock (to say nothing of a possible hernia through the scar), which operation would not promise any immunity from the disease.

MALIGNANT ENDOCARDITIS; DEATH; AUTOPSY.

BY C. ELLERY STEEDMAN, M.D.

A. B., merchant, aged forty-seven, was subject to rheumatism, and had an acute attack some years ago, which left him with a diastolic murmur under the right clavicle. In August, 1889, he had suffered, as had a brother and sister, from renal calculus. . . . In September, he had arthritis in left elbow and right

¹ Read at the meeting of the Boston Society for Medical Improvement, April 28, 1890.

foot, with considerable pain. The attack was subacute, easily yielded to salicylate of sodium, and lasted ten days. He returned to his counting-house at once, and on the third of October I was desired to see him again. He had had a chill, sweating, and high fever; complained much of the right ankle, of great weakness, headache, constipation, and a little confusion of mind. The temperature was 103.2°, the pulse 90, strong and regular. The murmur continued under the right clavicle. At six the same evening the temperature was 104°; at ten the next forenoon it dropped to 97.6°, with sensation of chilliness. The next day it ranged from 100° to 102.4°; and the following twenty-four hours between 100° and 101°, with amelioration of all symptoms. On the eleventh day of the disease the fluctuations of the mercury were from 99.2° to 103°; and on the thirteenth there was a fall from 104° at noon to 97.5° the next forenoon; in the night of the fifteenth day there was a rigor at 99.6°, and the next morning the thermometer indicated 104.6°. On the thirty-fifth day the temperature ranged between 99.8° and 105.8°, the highest reached. Delirium was first noticed on the sixteenth day, and was more or less present during the sickness; vomiting was infrequent. The tongue was clean and moist till the last week of his life, and his expression did not greatly alter. There was much irritability, little disturbance of vision, no cyanosis. The rheumatic pains disappeared after the first week as do the rachitic pains of typhoid fever.

It was near the end of the first week that a new cardiac murmur was noticed with the systole at the apex; the apex was not easily defined, the area of dulness seemed slightly increased. In the aortic area there was on the twentieth day a slight systolic murmur propagated upwards, a loud diastolic sound downwards; in and about the mitral area was heard an aortic systolic murmur not present when this illness began; a slight crepitus was heard in the middle of both backs. At this date there was no swelling of the abdomen, no spots on the skin; the epigastric and cremasteric reflexes absent; the plantars responsive; answers and questions were prompt and accurate, though the patient seemed apathetic. On the thirty-fourth day he was harassed by cough increased by lying on his side, and without expectoration; his tongue was coated; the liver below the margin of the ribs a little tender, as was the region over the heart; the mind not wholly clear; the jugulars slightly distended; the first sound at the apex and the systolic murmur less distinct; some crepitus in tricuspid area; dulness of left back, with general crepitus, also present in the front to a less degree. On the thirty-fourth day there was an involuntary dejection. From the thirty-fifth to the thirty-ninth day there was a gradual fall of temperature from 105.8° to 97.6°, from which it shot the next day to 103.5°, and then decreased till the forty-fourth day, on which he died.

The autopsy was made twenty-four hours after death, in my unavoidable absence, by Dr. S. Crowell, to whom I am obliged for the following notes. Drs. Benjamin Cushing and F. C. Shattuck were present.

The pleura, pericardium and peritoneum contained some fluid light in color, partly due, doubtless, to the undertaker's operations. Kidneys enlarged, dark in color; one contained numerous uric acid calculi, otherwise normal. Liver enlarged, with nutmeg appearance. Spleen enlarged, dark red, friable; had an old

infarction. The lungs were not adherent to the pleura; no indurations in their substance, air and fluid being squeezed from them. The heart enlarged, the aortic cusps were rather thickened, insufficient, and the seat of numerous warty vegetations, one of which hung freely movable on its pedicle downwards toward the ventricle. This vegetation, in striking against the cavity opposite its attachment, seemed to Dr. Fitz (who studied the specimen later), to have lighted up inflammation, which resulted in a myocarditis and abscess; pus of a dark color, and mixed with a degenerated necrotic tissue, issued from an opening in the ventricular wall; the pus cavity in the heart muscle was over an inch in depth.

I was efficiently aided in this case by the support and counsel of Drs. Cushing and Shattuck.

The patient presented no signs of anything more serious than the ordinary rheumatic endocarditis till the second week. After the first visit the temperature was not remarkable for six days; then it took its flight upwards to 104°, and the systolic murmur was added to the diastolic. The patient's family had suffered a sad experience with typhoid fever, and were impressed with the similarity of the symptoms to those they had been frequently called on to witness. A physician not familiar with the patient's history might have easily been misled about the character of the disease; and the strong, good pulse would have justified a favorable prognosis nearly to the end, had not the condition of the heart (of which there was no complaint or sign except the physical ones) been suspected.

LARGE PAPILLOMATOUS CYST WITH ASCITES; LAPAROTOMY; WOUND OF THE BLADDER WHICH LAY UNUSUALLY HIGH; SUTURE OF IT WITH COMPLETE RECOVERY.¹

BY A. T. CAROT, A.M., M.D.

In June, 1889, I saw Mrs. H. F. H., in consultation with Dr. H. W. Boutwell of Manchester, N. H. The patient was an emaciated woman of fifty-two. Her menses had ceased when she was forty-four, and she had been in apparent good health until one year before my visit, when she noticed that her abdomen was increasing in size. This enlargement was at first more noticed in the right side than in the left. She steadily lost in flesh and strength during the year and the swelling as steadily increased. Six weeks before she came under observation the legs became swollen, and a large protrusion of the vaginal walls became very troublesome. The pressure upward became so great that she suffered greatly from dyspnea and was unable to lie horizontal.

When seen, the abdomen was enormously distended with ascitic fluid, so that examination by palpation was extremely unsatisfactory.

Nothing could be detected in the heart nor in the condition of the urine to account for this accumulation of fluid, and there was nothing in the symptoms to point to the liver as the seat of trouble. In the absence of evidence in any of these directions, it seemed very probable that an abdominal tumor had given rise to, and was now masked by the ascites. This suspicion was strengthened by the patient's observation that the swelling of the abdomen had started in the right side, and had afterwards become general.

¹ Read before the Boston Society for Medical Improvement, April 28, 1890.

With the object of further observation she was sent to the Massachusetts General Hospital.

On June 27, 1889, I tapped the abdomen and drew off sixteen quarts of dark, brownish fluid which contained many blood-cells and some large compound granule cells. After the removal of the fluid, a tumor as large as an adult head came into view, rising up out of the pelvis, and a little to the right of the median line. Portions of this felt elastic, as if cystic in character; but the larger part of it, especially that portion towards the pelvis was quite firm. It was so fixed in the pelvic region that it altered its position but little on change of position.

A strong suspicion of malignancy was entertained, both on account of the physical qualities of the tumor, and from the character of the fluid removed. It was, however, decided to do an exploratory operation and to remove the tumor if it were found possible.

July 5, 1889. Laparotomy was done. The incision was made midway between the pubes and umbilicus. At a distance of four and a half inches above the upper edge of the pubes the incision which was carried straight down through the abdominal wall, opened the bladder, without entering the peritoneum. This opening was closed by an interrupted suture of fine black silk, and then the peritoneum was opened in the upper part of the wound. The tumor, which was very adherent in the pelvis, was peeled out after some difficulty; and there being some persistent oozing of blood from the separated adhesions down in the pelvis, a glass drainage-tube was put in and the abdomen was closed by interrupted silk sutures including the peritoneum.

The tumor was a multilocular cyst, with considerable papillomatous growth in the lower portion. This papilloma had nowhere broken through the cyst wall, nor implicated the peritoneum.

The recovery was uneventful, though somewhat slow on account of the weakness of the patient. The urine was drawn through the catheter for the first week and some irritability was caused by this frequent catheterization. The bladder suture held perfectly, however, and the wound healed by first intention.

This case was interesting for several reasons: The diagnosis was difficult as the tumor could not be felt while the ascites was present, and after the fluid was drawn off, the character of the tumor and its firm adhesion to the pelvic organs made it seem malignant. This suspicion was strengthened by the bloody character of the surrounding fluid. The result of the operation shows the importance of doing laparotomy in all cases in which there is a possibility of doubt as to the kind of tumor or the feasibility of its safe removal.

The position of the bladder in this case was quite exceptional, and led to its being wounded by an incision at a point where there was no reason for anticipating such a danger.

Usually when the bladder is wounded in laparotomy, the injury passes through the peritoneal surface, and after suturing, the adhesive inflammation of the peritoneum greatly promotes the adhesion of the wound. In this case the incision did not go through the peritoneum, but only involved the connective tissue in front of the bladder. It was like the wound made in suprapubic lithotomy, and in these wounds, primary intention is much rarer than in injuries to peritoneal surfaces.

Care was taken in applying the sutures, to include all of the outer layers of the bladder wall, but not to penetrate the mucous membrane.

The accumulation of urine in the bladder was prevented by frequent catheterization, and the ready healing shows that no leakage took place.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR MEETING, April 28, 1890, the President, DR. W. L. RICHARDSON, in the chair.

DR. A. T. CABOT showed a

PIECE OF CATHETER

about four inches long, which he had removed from the bladder of a man of seventy. The specimen was interesting as showing how rotten one of these web catheters becomes in the bladder, and how easily they may be cut up and removed with a lithotrite. It must rarely happen that a supra-pubic or other cutting operation is needed for the removal of such a fragment. In this case a stricture of the urethra somewhat complicated matters. This was divulsed as the first step in the operation; and the reporter said that he preferred diversion to urethrotomy in such cases, where he was going to pass the instruments through the urethra afterwards, as he thought diversion left the passage smoother, with less likelihood of there being pockets in which instruments might catch.

Dr. Cabot reported a

A CASE OF SUTURE OF THE BLADDER¹

for a wound made during a laparotomy for a large papillomatous cyst.

DR. J. HOMANS, 2ND, reported

A CASE OF CHRONIC PERITYPHILITIS.²

DR. CABOT: One point which Dr. Homans made is, it seems to me, an important one, and one in which I should differ decidedly from him, that is, that this condition of the appendix which was found at the autopsy showed that the appendix was not the cause of each individual attack. We know from recent cases published in the journals, how even a comparatively short time, a few weeks, after an attack which was evidently caused by the appendix, the appendix has been removed and there has been no ulceration through its wall, and it seemed in a tolerably normal condition, slightly thickened as to its walls, but not otherwise altered. I think the power of reparation is very great in the appendix; and it does not seem to me impossible that the cause of each of these attacks was ulceration of the appendix, which subsequently healed, and that an adhesive inflammation started from this ulceration, and left the cake of tissue which was described.

DR. F. C. SHATTUCK: The reader mentions an intense jaundice, and yet the common duct seems to have been patent. Is there any report as to the cause of that jaundice?

DR. HOMANS: A probe could be passed at the autopsy, but the supposition was that the mass of connective tissue, by the mere force of its pressure, closed it so that the flow of bile was stopped.

¹ See page 83 of the Journal.

² See page 81 of the Journal.

DR. CABOT: In connection with the question of removal of the appendix and the severity of this operation, I should like to report a case I had early in the year, in which, upon removing a malignant tumor of the ovary, the appendix was found buried in the tumor. I first dug out the piece of tumor growing into and upon the appendix, and laid it to one side while I removed the mass of the tumor. Afterwards I tied the appendix off at its junction with the head of the colon, and then inverted and stitched the end so as to bring the serous coats approximately together. In that case, as in many of the other cases of removal of the normal appendix, there was no reaction. The case did perfectly well, and it seemed as if the interference with the appendix had added nothing to the severity of the operation. I think that the removal of the appendix is an operation of comparatively little severity.

DR. HOMANS: My idea was, that as a result of three or four attacks there would be various bands of adhesions, with certain amount of abnormal structures, and that the whole would be in a state of sub-acute inflammation all the time. The mere removal of the appendix will not straighten out those bands. It would be the same thing as a man who has had a severe attack of pleurisy where, the adhesions still remaining, and portions of the lung still compressed perhaps, those adhesions always stay, and he is liable to have another attack: so it seems to me, with the coils of intestine lying round and adhesions going from one to the other, that there is left behind an amount of inflammatory structure of abnormal condition after the appendix has been removed. It does not seem probable that the removal of the appendix will prevent the recurrence of attacks, though it may make them somewhat less likely to occur; yet I should say it would affect the chances of their recurring to a comparatively small extent.

DR. CABOT: Do you think the inflammatory adhesions left there are themselves the source of inflammation subsequently?

DR. HOMANS: The source of pain. They might cause a slight kink in a coil of intestine.

DR. CABOT: I agree to that, but I think the appendix is, with few exceptions, the cause of the recurring attack.

DR. C. E. STEDMAN³ and DR. F. C. SHATTUCK⁴ each reported

A CASE OF MALIGNANT ENDOCARDITIS.

DR. B. CUSHING read a case with autopsy showing how extensively the heart may be diseased without constitutional symptoms.

DR. CABOT: In Dr. Cushing's case the murmur was a very loud systolic one, difficult to locate. We had no stethoscope with us so that we relied upon our ears. That and one other case are the only instances of malignant endocarditis I have seen, and unfortunately in the other one there was no autopsy obtained. I saw the case for my father in his absence and he subsequently took charge of it. The first symptoms were those of bronchitis. On examination I heard a systolic murmur over the aortic valve which lasted a few days and disappeared; never to be reproduced. The patient ran down with rather high temperature, and had, I remember, an abscess over one malleolus

³ See page 82 of the Journal.

⁴ See page 79 of the Journal.

and another on the top of the head, with one or two others at different points under the skin.

DR. BLODGETT: I am reminded by the very interesting cases which have been reported to-night of the first case of this disease of which I have any knowledge as having been reported in this vicinity, which occurred some years ago in the practice of Dr. Grace Wolcott. The patient was a woman about forty years of age, who had had the preliminary symptoms referable to rheumatism, which have been mentioned as preceding very often cases of endocarditis of this character. Dr. Wolcott noticed, soon after, the occurrence of a mitral murmur, which had not heretofore been present, and which increased from day to day for several days. By the kindness of Dr. Wolcott I saw the case in consultation, and we both arrived at the same opinion, that it was a case of progressive endocarditis; and we could account for its peculiar symptom-complex in no other way than by the supposition that acute inflammatory and destructive processes were going on in the heart, producing the murmur which increased from day to day. The patient lived about ten days from the discovery of the cardiac murmur, and death took place from the lesion of the heart, as I remember it, more than from any other ascertainable cause. In this case there was the foudroyant course of the disease, and it was accompanied with symptoms of acute septic infection. No attempts were made to cultivate bacteria. There were frequent chills and symptoms similar to those which would accompany pyæmia in any other part of the body. The heart was removed and presented before the Clinical Section at the time at which the case was reported. The heart presented, as I remember it, a distinct perforation through the substance of the mitral valve, of ulcerative character with ragged edges and the appearance of inflammatory conditions affecting the free edge of the valve, and to some extent, the chordæ tendinae.

I have during the past winter had a case that reminded me of ulcerative endocarditis which has followed another course. A lady of about twenty-two years suffered from the prevailing epidemic in December, but was not confined to her bed. I was called to see her some days subsequently when she had been prostrated by a chill, and I then found the evidences of acute pneumonia confined to the left lower lobe. It ran its course in the ordinary way. On the fifth day a systolic murmur was heard over the base, which I had not been able to detect before, and concerning which no history of previous heart disease was ascertainable. I felt quite certain that if any condition referable to the heart had previously existed it would have been discovered. That murmur increased for a certain number of days and at the end of a fortnight was at its height, remained persistent several weeks and gradually diminished; but during its subsidence there occurred an acute inflammatory process located in the region of the left ovary, and which I thought was connected with the ovary. I made no vaginal examination, but by the application of hot poultices, the administration of anodynes, and by other measures which suggested themselves from time to time as the case progressed, the inflammation finally subsided, the swelling was reduced and the local process became very much better. Following this there developed a typical phlebitis of the left leg, which ran its course in about four weeks, and from which the lady is still suffering.

This case corresponds very well I think with some that have been reported of supposed malignant or perhaps, ulcerative processes of the heart with subsequent inflammatory or septic affections of various parts of the body. It would seem very possible in this case to depend upon a cardiac lesion which had not previously existed, which was present to a certain extent during a considerable interval, and which subsided until its presence could not be detected. Whether that is a case of the character mentioned to-night as among those who recover from this disease I may never be able to ascertain. I present it as a possible case in which the chief symptoms of that rather uncommon disease were present, and it is the only case that has ever come under my personal observation in which recovery has followed.

DR. F. C. SHATTUCK: Patients have been sent to insane asylums as suffering from acute mania whose disease was malignant endocarditis. A very interesting case of this affection in which such a mistake was made was reported by Dr. Truax in the Section of Clinical Medicine at the last meeting of the American Medical Association at Newport. With regard to Dr. Blodgett's case there are two points that strike me: one is the great care that we must exercise in the interpretation of systolic murmurs. A diastolic murmur is on the chances organic, but so many systolic murmurs are dynamic or haemis that I think we have got to be pretty careful about them. This very winter a patient at the hospital — I forget what the disease was — during the last few days of life developed a tremendous to-and-fro murmur over the heart, harsh, rasping. At the autopsy the heart and pericardium both were normal. In Dr. Blodgett's case I suppose he would hardly attribute the swelling of the leg to embolism. Thrombosis would seem to be the more probable cause.

DR. BLODGETT: I considered the first inflammation in that region as probably the cause of the thrombosis of the vein, not an embolism of the artery.

DR. WHITNEY showed a specimen of

OSTEO-CHONDRO-MYXOMA OF THE RIGHT THIGH.

The history is briefly that of a man who, for the last four years, has had a rapidly growing tumor of the upper part of the right thigh; and which, when first seen a short time ago by Dr. S. J. Mixter, was considered inoperable. The foot was everted, and the posterior part of the growth ulcerated and necrotic.

At the autopsy made to-day by Mr. F. B. Mallory, of the Medical School, the head of the bone and acetabulum were found to have been destroyed; but the pelvis itself had not been perforated, and there was no internal metastasis. The bulk of the tumor was made up of soft gelatinous and sago-like looking material, covered by a sort of harder outer shell, in which were plates of bone, the thickest and largest forming a continuous, more or less irregularly flattened outgrowth from the shaft of the femur. Microscopic examination showed this to be made up of a homogeneous ground substance, giving a reaction for mucin. In this were imbedded numerous round, spindle and star-shaped cells anastomosing by long, very fine filaments. In places areas of true cartilage were met interspersed with bone. So that the growth should properly be called an osteo-chondro-myxoma. The starting place is either from the medullary canal or at the point where the head joins the shaft. But at

present it is impossible to say which, as the destruction and new formation of bone have been so extensive.

THE NEW YORK ACADEMY OF MEDICINE.¹

SPINAL SURGERY: A REPORT OF EIGHT CASES.

THE next two cases, Dr. Abbe said, were of unusual interest, as they showed a field in which the extreme nicety of diagnosis does credit to the physicians in charge, and surgical relief follows closely.

CASE V. Extra-dural tubercular tumor of the spine; complete paraplegia; operation; recovery.

The patient, twenty-two years of age, was taken with pain in his back in January, 1888, and admitted to St. Luke's Hospital in March. The spine was flexible, and without deformity, though a very slight fulness was seen in the soft parts to the right of the ninth and tenth dorsal spines. During March the sense of touch was dull in his legs, and the muscular power somewhat weakened. A line of hyperesthesia formed about his waist. Two weeks later he could not stand without support, and he had uncontrollable twitches of the legs, which had become quite anesthetic. He had constant intercostal pain, with girdle pains about the limiting line of disease. Incontinence of urine and feces followed; an active hectic set in, and he rapidly wasted away. During the week before operation he failed so rapidly that death seemed imminent.

On May 26, 1888, Dr. Abbe made a free incision and removed the spines and arches of the eighth, ninth, and tenth dorsal vertebrae. Outside the carious arch of the ninth was a half-ounce of thick pus; but within, and filling the vertebral canal, was a small quantity of inspissated pus and a large amount of dense neoplasm, evidently tubercular. It extended up and down the canal for two and a half inches, and it was thoroughly curetted from the cord by Volkmann's spoon, until sound bleeding tissue was left on every side. The cord was firmly compressed against the anterior wall of the canal. The wound was lightly packed with iodoform gauze, and allowed to granulate; and a plaster jacket was applied over all. The patient made a rapid and complete recovery, and remained perfectly well in every respect for more than a year. Recently, after the confinement of the winter, he has had an abscess form in the cicatrix which had been so long healed, and Dr. Abbe had to curette a sinus remaining from it which led down to the bone. There has been no affection of the cord, however, and he hopes very soon to heal the sinuses, though they have a distinctly tubercular appearance. (This patient was shown.)

CASE VI. Pressure paraplegia from extra-dural sarcoma; operation, with complete removal of the tumor; death on ninth day.

The patient was forty-two years of age. Three years ago, while placing a pedal under a heavy piano, the instrument was let down and pressed heavily on his back, and he suffered pain from this for several days. Six months later, while lifting the corner of a heavy piano, he was caught by an excruciating pain in the back. In January, 1889, he twice jarred his spine severely, and in July of that year he first felt a decided, though not severe, pain in his back at the site of the present trouble. After this, paralysis of the lower part of the body came on, and in October, 1889, he

was seen in consultation by Dr. E. C. Seguin, who made a diagnosis of pressure paralysis and advised early operation. In January, 1890, the patient was brought from his home in Toronto to New York, and placed under the care of Dr. R. F. Weir. Drs. Seguin and Weir found on examination a slight fulness of the eighth dorsal spine, and advised a month or six weeks of orthopedic treatment; hoping that the pressure might be from Pott's disease and that a natural relief of intravertebral pus might put an end to the paraplegia without operation. The treatment adopted was followed by no improvement, and during its continuance he had a fortnight's illness with acute nephritis and a temperature of 102.5°. Dr. Weir having gone to Europe the case was transferred to Dr. Abbe. On March 20th, the day before it was arranged to operate, he had an unaccountable chill, with a temperature of 104°. This attack lasted two weeks before his temperature became normal, and it, as well as the previous one, was probably due to slight septic infection.

On April 16th, Dr. Abbe operated. On removing the arches of the eighth, ninth, and tenth vertebrae and the pedicle of the eighth, a firm dark growth was found to fill the vertebral canal, compressing the cord to the left side and flattening it somewhat forward; so that it represented scarcely more than half its normal bulk. It was readily removed by blunt resection from the dura, which was left with a quite natural appearance. The growth bulged backward between the arches, laterally between the pedicles, which it softened, and forward into the body of the eighth vertebra and at one side into the sub-pleural space; and from all these sites it was removed by Volkmann's spoon. Not a trace of pus suggestive of tubercular caries was anywhere seen. The wound was packed loosely with iodoform gauze. The patient endured the operation very well and was in excellent spirits for four days when hiccup and vomiting set in. He finally became so exhausted by these that he died on the ninth day; death being preceded by delirium. The muscles of the legs began to react to electricity on the fifth day; but no return of sensation or voluntary motion. The tumor was carefully examined by Dr. J. S. Thacher, who found it to be a round-celled sarcoma, without trace of leucocytes, giant cells, or tubercular material.

Dr. Abbe said this case was of special interest as illustrating the differential diagnosis between myelitis of the cord and pressure of the paraplegia of tumor, and he read a letter which he had received from Dr. Seguin relative to that question.

CASE VII. Intractable brachial neuralgia; nerve stretching, amputation, and finally intra-dural division of the sixth, seventh and eighth cervical nerves.

CASE VIII. Intractable brachial neuralgia; intra-dural division of the posterior roots of the sixth, seventh and eighth cervical and first dorsal nerves.

In neither of these cases was the result of the operation very satisfactory, though the pain appeared to be very much less intense and of a different character from that experienced before it. The basis for the operation in question, Dr. Abbe said, was the fact that sensory conduction is isolated in the posterior root, which is easily operated upon within the dura. Experiments recently made by Singer, Horsley and others to study the ascending degeneration after this section in monkeys showed that a speedy and complete degeneration backward into the cord resulted from it. This would give the desired destruction of an inflamed or

¹ Report of Meeting of May 15, 1890. Concluded from page 65 of the Journal.

diseased nerve to its very ultimate fibres. In his two cases there had remained all the anaesthesia obtained at the operation. Pain, however, had apparently recovered, though much milder. There was often simulated pain in those who had acquired the morphine habit; but in these two cases he believed it to be genuine. His conviction was that if all five roots had been cut the chances of recurrence would have been less.

In conclusion, he said that while we were not warranted in taking a sanguinary view of the results of operation, yet surgery, with its possibilities ever looming up, ought not to occupy the ultra-conservative ground of the past in this field. The scope of operative work might never be a large one; but it would probably not be as small as heretofore.

DR. JOHN A. WYETH said that he had been struck with the fact that in all the traumatic cases the seat of trouble was in the vicinity of the eleventh dorsal vertebra, and that this was also true of two traumatic cases of his own. In the surgery of the spine he would suggest the following classification: In the first of two divisions he would place all cases of compression by bone, dividing these into classes; first, those in which the compression was gradual, as in Pott's disease, and, second, those in which there was compression and more or less destruction of the cord from sudden violence. In the second division he would place the cases of compression by tumors, dividing the latter into intra-dural and extra-dural tumors. In our present state of knowledge he believed the cases where there was destruction of a portion of the cord were practically incurable; and this seemed likely to continue to be the case, unless it should become possible to remove the body of a vertebra, and thus enable the surgeon to bring together the healthy portions of the cord situated above and below the part that was destroyed. This was an operation, however, which he should not care to undertake or to witness at the present time. As to tumors of the cord, those which were intra-dural were naturally more dangerous than those outside the cord, and their removal afforded smaller chances of a favorable result.

He then gave an account of the two cases of fracture on which he had himself operated. In the first there was complete recovery, notwithstanding the fact that the patient had been paralyzed for more than two years previously. In the second case the cord was found to be somewhat flattened at the seat of trouble. There was considerable inflammatory lymph binding the cord very firmly to the dura; and the adhesions between the cord and the dura were broken up with the finger. The injury had been received on the 16th of September last, and the operation was performed seventeen days ago. As a result of the operation sensation was immediately recovered down the entire lower extremities. Motion was also restored to the two great toes, but up to the present time the paralysis of motion had been relieved only to this extent. From his own observation and reading he could not doubt but that in many cases of compression, and especially those of traumatic origin, the patients could be restored to usefulness by means of operative interference.

DR. A. P. GERSTER said that an obstacle to the restoration of function in cases in which the spinal marrow was divided was the area of cicatrical tissue lying between the separated ends. He did not know whether or not experiments had been made on animals to find out whether, if the divided ends could be united

the function would reappear; but, from the experience met with in the case of divided nerves, it seemed probable that it would. The matter was certainly worthy of investigation, and even desperate operative measures he thought were justifiable in such cases, on account of their hopeless character. The technical difficulties of bringing together the divided ends of the cord could no doubt be overcome by practising the procedure on the cadaver. Furthermore, he did not see why the extreme measure referred to by Dr. Wyeth, of removing an entire vertebra, should not be resorted to under certain conditions. If he thought such an operation would enable him to restore the functions of the lower portion of the cord he would not hesitate to perform it, provided he should first have demonstrated its practicability by experiment. He would not think of undertaking it, however, until it had been shown upon animals that such a restoration of function was possible by the uniting of the severed ends of the cord.

His personal experience in spinal surgery had not been extensive. Eleven years ago he had had at the German Hospital a case of new growth involving five of the vertebrae and causing paraplegia. It had originally, no doubt, been sarcomatous in character, and when seen by him it had become largely infiltrating. He succeeded in removing the greater portion of the mass, and in doing this he had to scrape some of it from the dura. The latter had become softened, and it gave way at some points; allowing a considerable amount of cerebro-spinal fluid to escape. The immediate results of the operation were very satisfactory, sensation and motion in the paralyzed extremities both becoming much improved. Later, however, a relapse occurred, and the case terminated fatally.

A second case of his had a more favorable result. It was one of vertebral tuberculosis of long standing in a lad fourteen years of age, who was admitted to the Mt. Sinai Hospital in December, 1888. In May, 1889, rapidly increasing paraplegia set in, and within a fortnight it was complete. On May 24th it was decided to explore the local state of affairs. The laminae of the sixth and seventh dorsal vertebrae were removed by the chisel and mallet, and an extensive extra and sub-dural abscess was evacuated. Widespread confluent caseation of the soft tissues adjoining the intravertebral focus was found, and in the caseous masses were imbedded the roots of the nerves on both sides. The transverse processes of fifth, sixth, seventh and eighth thoracic vertebrae on the right, and those of the fifth, sixth and seventh on the left, were found carious and partially necrosed, and the pertinent costo-vertebral joints destroyed. Consequently, these transverse processes were removed, as well as the heads of the respective ribs. The bodies of the sixth and seventh vertebrae were also much disintegrated, and their broken-down constituents were gouged away. No immediate improvement in the paralytic symptoms resulted from the operation; but in the following August the power and functions of the lower extremities were re-established; and this restoration took place in the short space of ten days. By massage, faradism, and active movements the muscular power was so enhanced that by October the patient was able to support himself without external aid; while in December, when he left the hospital, he could walk very well and had only a slightly-discharging sinus in the back.

DR. MORRIS said that ascending and descending degeneration followed division of the cord; but it seemed

to him that if, in case of its accidental severance, we could get the two ends of the cord together within a few hours, we might hope for a restoration of function. The ends, it was found after division, did not retract very far, for the reason that the spinal nerves are given off at short intervals. It seemed probable that it would be necessary to remove a vertebra; and in attempting this the most troublesome feature encountered would be the crowding together of the spinal nerves. The danger of such a procedure need scarcely be taken into consideration since the cases in which it might be thought of were of such a very desperate character. He had at present under his care a boy eleven years of age who had been shot with a twenty-two bullet in the line of the tenth dorsal vertebra, with the effect of producing paraplegia. He first saw the patient seven days after the injury, and he immediately cut down and opened the spinal canal. He removed an articular process which was found pressing upon the cord; and this was at once followed by improvement in both sensation and motion. In the right leg the recovery was now almost complete, but in the left the paralysis still continued to a very considerable extent. He was not able to find the bullet which had, no doubt, lodged somewhere in the spinal cord.

DR. R. H. SAYRE urged immediate operative interference in recent traumatic cases, but thought there were many cases of paraplegia resulting from Pott's disease in which a cure could be effected without resorting to operation. Cases which did not yield to systematic treatment directed to Pott's disease within twelve months, however, he said might very properly be looked upon as suitable cases for operation.

DR. SACHS said that up to the present time the results that had been obtained in spinal surgery were not especially gratifying. As a neurologist he thought that surgeons should select their cases for operation with more care than they had hitherto done. With Dr. Sayre he believed that recent cases presented the best opportunities for operative interference. If the cord were separated into parts, however, there was in his opinion not much hope of accomplishing anything. In cases in which the symptoms had become less marked than they were at first, as was the case in one of Dr. Wyeth's patients, there was a much better chance for success, since the amelioration indicated that there had not been a total destruction of tissue. Dr. Abbe, he thought, was deserving of great credit for demonstrating that such good results could be obtained in tuberculous cases as were presented in the patient he had exhibited. Formerly the opinion had been that no operation ought to be undertaken in cases of this character. He had been a little puzzled to understand why in some of the cases reported by surgeons so many laminae had been removed. As a rule, he believed this was entirely unnecessary, since, if proper care were observed in diagnosis, the lesion could ordinarily be located with very great accuracy. Operations for the relief of neuralgic trouble seemed to him to be the most objectionable in the whole range of spinal surgery. Judging from the results obtained by Dr. Abbe in the two cases he had reported, no improvement whatever was to be expected from them, and, in any event, this was certainly a very radical method of attacking neuralgias. It was to be remembered that pain was not the only symptom that was likely to result from trouble involving the posterior spinal roots. Vaso-motor disturbances especially,

as well as neuralgia, would be apt to follow. As these two cases showed, unless we had good reason to infer the existence of organic disease of the posterior spinal roots, it would not be well to interfere in this way.

DR. ABBE said, in regard to neuralgia, that no sane man would think of operating in ordinary cases. In the two patients upon whom he had operated, however, the trouble was so exceedingly aggravated and so utterly unamenable to all other remedial measures that the procedure seemed to him entirely justifiable as a last resort. That such operations might be attended with success was shown by a case in England reported by Bennett. It was one of sciatic neuralgia, and though the patient unfortunately died of apoplexy twelve days after the operation, from the time of the latter there was complete freedom from the pain which before had been so constant and so excruciating. In his own two cases he wished it to be distinctly understood that the character of the pain experienced was entirely altered after the operation. In both patients he believed there had been a hysterical element, although he had tried to eliminate this as far as possible. Both were also still taking morphia largely, and such cases could not be depended upon. Moreover, it so happened that both of these men were trying to get pensions on the ground of disability from the pain. While, therefore, he really believed them to be genuine sufferers, he was not at all sure about the matter. In fractures of the spine he thought the operation should very rarely be done. He was not positive, however, that restoration of innervation to the lower segment of the cord could not be successfully accomplished after further experiments had been made upon animals. But to bring the divided parts of the cord directly together again he believed could only be accomplished by removing one of the vertebrae, and this did not seem possible to him without destroying the patient's life.

AMERICAN NEUROLOGICAL ASSOCIATION.¹

ON INGRAVESENT APOPLEY.

DR. C. L. DANA read a paper with this title. He said that there were three sets of intra cranial blood-vessels, those in the dura, those in the pia mater, and those in the substance of the brain. We had correspondingly three types of intra-cranial hemorrhage. The central hemorrhages were far the most common, and presented a tolerably uniform clinical type. There was one form, however, which had seemed to have escaped critical attention, though it could not be excessively rare. In 1876, Dr. Broadbent had reported six cases of what he had termed "ingravescient apoplexy." In 1889, M. P. Prusch, of Montpellier, had also reported a case of the same character. The writer had met two cases presenting the general clinical characters of ingravescient apoplexy, but was able to make an autopsy upon only one, of which the data was as follows: A woman was brought to the hospital May 1st, without any history. She was in a stupid condition but not unconscious, and she was at first thought to be intoxicated. Examination showed, however, some hemianesthesia of the left side and slight hemiplegia of the same side. The right pupil was slightly contracted, temperature normal, pulse tense. Next day the pa-

¹ Report of the Sixteenth Annual Meeting, held at Philadelphia, June 4-6, 1890. Concluded from page 63 of the Journal.

tient's mind was clearer; she answered questions and recognized those about her. But the hemiplegia was very much worse, and the analgesia no better. Toward night she became more stupid and finally comatose; edema of the lungs developed. No contractures of the paralyzed side were noted. The temperature rose and the patient died next day, May 3d.

At the autopsy the brain was found congested. Pressure over the supramarginal gyrus showed that there was a softened place beneath it. The brain was placed in boroglycerine and alcohol, and opened later by vertical section. There showed a clot in the lateral ventricle and some blood in the third ventricle. Beneath the supramarginal gyrus was a large hemorrhagic focus about one inch and a half in diameter. This extended forward and downward cleaving the external capsule. The hemorrhage had finally extended downward and inward, and broken into the lateral ventricle. Prush had attempted, on the slender basis of seven cases, to erect "ingravescence," or, as he called it "progressive," apoplexy into a distinct type. This seemed to the author to be somewhat premature. The history of his case was not exactly like those of Broadbent's in respect to retention of consciousness; and the hemiplegia was relatively less marked. Yet anatomically it was one of the "cleaving" hemorrhages due to rupture of a posterior branch of a lenticular artery, and running the same course as was described by Broadbent. The hemianesthesia seemed to the author to be a very distinctive point. Practically the question came up as to whether in such cases trephining would be justifiable. In general, the idea of trephining for non-traumatic hemorrhage was not to be entertained at all. But in ingravescence apoplexy it deserved consideration because here the hemorrhage was accessible, and because, unless some relief was given, it would surely break into the lateral ventricle and kill the patient. In all the reported cases, also, the patients were not old, were not syphilitic, and presumably had not extensively diseased arteries. In reaching hemorrhages in these cases, the best place to trephine would be a little below and in front of the parietal eminence. The surgeon should then explore downward and forward, care being taken not to injure the terminal branches of the Sylvian artery, which were in this neighborhood. In cases of "ingravescence" apoplexy, surgical interference, if undertaken, must be before the blood broke into the ventricles. This could be told by the sudden increase in the severity of the symptoms, and, if the blood was poured in rapidly, by contractures on the paralyzed side. The temperature changes were believed to be the same in the ingravescence as in ordinary apoplexy.

DR. MILLS had seen a number of such cases. The results of his experiments had led him to think that the trephining, if done at all, should be several inches back from the temporal lobe, along the junction of the second and third temporal convolutions. He had known of patients with intra-ventricular hemorrhage recovering independent of the question of trephining.

DR. W. SINKLER said Dr. Dana had referred to the question of temperature. He had recently had a patient die from enormous hemorrhage into the ventricle and the temperature at death was 108°.

DR. WEBER questioned the utility of trephining in those cases in which the history was rupture.

DR. MILLS said the advantage of trephining was that it gave the patients a lease of two or three weeks as

the breaking into the ventricles did not take place until late. By trephining and finding the bleeding point, there was perhaps a chance of controlling it.

DR. DANA said that trephining was purely empirical, and he could not say whether it was good or not.

PONS LESIONS IN THEIR RELATION TO ASSOCIATED EYE MOVEMENT PARALYSIS.

DR. SPITZKA presented this paper by title, accompanied by the demonstration of a specimen of a minute focal lesion of the dorso-caudal part of the pons, unilaterally situated in and near the abducens nucleus. In connection therewith, Dr. Putnam mentioned one of similar location to Dr. Spitzka's, in that the presumable lesion must have occupied the same position.

A CONTRIBUTION TO THE PATHOLOGY OF THE SOLITARY TUBERCLE OF THE SPINAL CORD,

by DR. HEUTER.

The paper consisted of a report on the clinical history and pathological anatomy of three hitherto unpublished cases of solitary tubercle of the cord, and of brief analysis of the clinical and pathological features of the condition based on these cases, and in those which had been collected from the literature on the subject. It was believed that the clinical history of solitary tubercle of the cord could be more accurately written than heretofore, with the help of the facts that had been recorded in the given cases. The uniformity of the symptoms in different cases, especially as regarded their course, the rapidity with which the usually unilateral symptoms became bilateral, the comparative insignificance of the irritative phenomena, and the frequency with which the signs of tubercular disease in other organs existed, were characters of solitary tubercle of the cord which might help in this distinction, both from tumor of the membranes and from other varieties of tumor of the cord.

DR. SACHS said it was some years since his paper on this subject was written. At that time he had thought that the very slow development, the strictly unilateral symptoms and subsequent spread of the disease involving both halves, would constitute a basis for diagnosis of tumor of the cord. Now the point came up with regard to the possibility of distinguishing between extra- and intra-dural tumors.

DEMONSTRATION OF SOME SPECIAL ANATOMICAL CHARACTERISTICS IN THE BRAIN OF A DISTINGUISHED SCIENTIST.

DR. B. J. WILDER presented the brain of the late Mr. Chauncy Wright, and demonstrated to the Association what he deemed striking anatomical points. One peculiarity specially dwelt upon was the existence of a very simple insula, instead of a complex one. Then the inhibition of the fissure of Rolando by an isthmus was so rare as to call for attention. Then in contra-distinction to the condition in other brains it would be seen that the central fissure above that point was shallow. The speaker urged his hearers to aid in every way possible the further investigations of comparative anatomical study in this field. To successfully effect this it was necessary to secure young human and apes' brains in every stage of development.

TUMOR OF THE QUADRIGEMINAL REGION WITH SPECIAL REFERENCE TO OCULAR SYMPTOMS.

DR. B. SACHS read a paper with this title. He had been fortunate enough to obtain two autopsies, during the past year, which bore upon this question, and also

several cases which were subjected to careful clinical examination. His first case was one of unusually severe tuberculosis cerebri. The main points of the history, which he had been able to complete, through the kindness of several colleagues, were these: E. L., aged three years, when first seen she had double ptosis, but no other ocular paralysis was observed. She was dull and listless, and had a pulse that ranged from 145 to 160, but with normal temperature. The mother had noticed a change in the child's disposition since an attack of measles nine months previously. The child did not care to play, but preferred to sit quietly in a chair all day long. She staggered in walking and occasionally fell. She had no epileptical attacks, and had vomited but once. Knee-jerk was absent. The right hand was weaker than the left. No anesthesia or ataxia. There was paresis of both latorv pulpetrani, the pupils being half covered. No nystagmus. Pupils were equal, moderately dilated, and reacted well to light and accommodation. December 28, 1888, the patient had come under Dr. Sachs' care. The condition at that time had showed great changes. Examination disclosed double and almost complete ptosis. There was no upward or downward movement of either eye. Both external recti muscles were thrown into clonic spastic condition when the attempt was made to use them. The interni were capable of very slight movement, but all the other ocular muscles were completely paralyzed. The accommodative reflexes were still distinct, and there was slight contractility to light. There was also slight left facial paresis. The vision was very much impaired. Although in a semi-stupor, the child could be made to walk, and then exhibited most distinct cerebellar staggering, walking with a broad base, and almost falling to the right side. The oculist reported plaques of choroidal atrophy below the macula of left eye. The reflexes were exaggerated, and there was occipital headache. The diagnosis of tumor of the corpora quadrigemina was given. The tumor was supposed to be associated with a general tubercular meningitis. The child grew rapidly worse, and after passing through several convulsive seizures, becoming blind, and finally developing left hemiplegia, died February 4, 1889. Autopsy showed the dura adherent to the skull and it had to be removed with the calvarium. The quantity of the sub-dural fluid was slightly increased. A solitary tubercle was at once discovered near the right lateral sinus, pressing into the lateral edge of the cerebellum and producing thrombosis of the lateral sinus. Other tubercles with large areas of softened tissue were found in the cerebellum. Deep examination of the brain showed the hemispheres to be healthy, with the exception of the small tubercular deposits along the paths of the blood-vessels. The cerebellum was the seat of the most profound changes. The base presented several unusual conditions. There was great thickening of the pia with small tubercular deposits between the corpora mamillaria and optic chiasm, and in the interpeduncular space. The thickening at this point was so great that both third nerves instead of lying across the crura, after removal of the brain, pointed backward, and the right, the sixth, was twisted out of its position. Section of the brain showed the tumor to occupy almost the centre of the tegmental division of the crus and had left a very small portion of the corpora quadrigemina and the brachia intact. The occipital head-

aches and the cerebellar staggering were the only symptoms which could be ascribed to the large tubercles in the cerebellum, though both these symptoms might be due to the lesion of the quadrigeminal region. It was probable that the sixth and seventh nerve nuclei were responsible for the symptoms pointing to lesions of those nerves, or that the basilar meningitis was at fault. Certain it was that the latter condition was late in developing, as for months the symptoms had been distinctly nuclear. In spite of the manifold morbid conditions, it was most remarkable that the ciliary muscles and the sphincter iridis had remained exempt during the entire period of observation. Considering the compactness of all cerebral structures in the crura, it would be supposed that there could be no difficulty in making a differential diagnosis between cases of tumor in this region, and a chronic inflammatory process.

CRUS LESION.

This was the title of a second paper by Dr. Sachs. Crus lesions were rarer than many other cerebral lesions, but their symptoms were well-marked. The case under consideration had some special interest, however, in connection with post-hemiplegic disturbances of motion and from this point of view, the results of the post-mortem examination were worthy of consideration. Seven years ago the patient, a woman, about fifty years of age, had had a dizzy attack one morning, and had found her vision rather blurred. There was a recurrence of the attack in fifteen minutes. There was no unconsciousness nor difficulty with speech, but when the patient attempted to walk she found she could not with ease. By morning she had almost complete left hemiplegia, she could not open either eye. At that time speech was heavy and indistinct, but from this she had recovered in three weeks. Hearing, taste and smell were altogether normal. The hemiplegia was never recovered from, the patient became somewhat unruly and demented, and was finally taken to the Montefiore Home where she had remained for many years. A few further details of the patient's chronic condition were elicited in examination. There had been no history of syphilis, but there was very marked atheroma of the peripheral arteries. In addition to the left hemiplegia, the patient had suffered amputation of the right leg above the ankle, for old necrosis of the tibia, fully six years before. There was rigidity of the left leg and increased knee-jerks of both sides. The wrist reflex was decidedly increased on the paralyzed side, but the left upper extremity was subject to the wildest ataxic movements. This would go on until the arm dropped from exhaustion, when it would remain quiet until aroused again by an effort to use the hand. She became extremely emotional, took very little nourishment and finally died. The diagnosis of crus lesion of the right side, probably softened from thrombosis, was made, which the autopsy confirmed.

ON THE GERM OF A COMMUNICABLE DISEASE DERIVED FROM A DOG, ALLEGED TO HAVE DIED OF RABIES, WHICH RETAINS RABIC CHARACTERS.

DR. RICHARD MOLLENHAUER exhibited some microscopic specimens taken from a dog which he had succeeded in rendering rabid by inoculation. The germ was a bacillus whose various growth-stages presented a uniform type.

A CASE OF INSULAR SCLEROSIS IN WHICH AN ATTACK OF CEREBRAL HÆMORRHAGE ARRESTED THE TREMOR ON THE HEMIPLEGIC SIDE.

DR. WHARTON SINKLER related the history of this case. The patient, a man aged sixty-four years, had always enjoyed good health until about ten years ago when he began to notice tremor in both hands, but worse in the left. In 1889 he had experienced an attack of left hemiplegia without loss of consciousness. Since that attack there had been no tremor on the left side, but a coarse tremor on the right side still persisted. The patient's appetite and general health had remained good. The hemiplegia continued about the same with no further involvement of the tremor.

REMARKS ON THERAPEUTICS AS APPLIED TO NERVOUS DISORDERS.

DR. W. R. BIRDSALL read a paper with this title. Early diagnosis he regarded as the most important factor for therapeutic success in diseases of the nervous system, as it frequently enabled the physician to check the course of a disease where marked disability had not yet resulted. Hygienic measures were considered of prime importance and pharmaceutical remedies as valuable accessories in the treatment of these diseases. All relation between storage and expenditure must be readjusted to the disturbance in equilibrium, and the aim of therapeutics consisted in bringing about such a readjustment. The modern craze for so-called physical culture, the author believed was bringing forth dangers as great as those it was sought to remedy, through over-training, improper training, training for brain workers, which fatigued rather than rested the brain, together with other faulty methods. Hydrotherapy he considered was much neglected, and electrotherapy overestimated. Next to hygiene cutaneous irritation was decidedly the most important therapeutic measure possessed by the neurologist. Surgical interference and the drugs usually employed by the neurologist were then briefly referred to.

DR. W. SINKLER believed in the use of drugs in nervous disorders. No doubt arsenic in chorea, hyosciamine or hyoscine in various tremors, the iodides and antisyphilitic remedies in specific diseases of the nervous system were all of value. He wished to put himself on record as not being a pessimist or nihilist.

DR. BRUSH said he wanted to accentuate what Dr. Birdsall had said as to the management of cases of nervous diseases. A great many could be better treated by other means than drugs. He should some day present some cases of insanity from drug poisoning. Once he used to try everything that came along, but now he made less and less use of drugs.

DR. L. C. GRAY said he was a believer in the efficacy of properly directed therapeutic measures in combination with everything else in the treatment of nervous disorders. Chorea in all its minor forms, neuralgias, functional nervous disorders, subacute or acute mental troubles, except acute mania, were all amenable to judicious therapeutical endeavor on the part of the neurologist.

The officers elected for the ensuing year were, President, Dr. Wharton Sinkler of Philadelphia; Vice-Presidents, Dr. C. L. Dana of New York and Dr. S. G. Webber of Boston; Secretary and Treasurer, Dr. G. M. Hammond of New York; Councillors, Dr. G. L. Walton of Boston and Dr. L. C. Gray of New York.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 24, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

CARDIAC DYSPNEA.

WHEN we consider the frequent coincidence of cardiac lesions with dyspnoea, we cannot regard it as surprising that in the infancy of pathological anatomy Rostan, noticing in a large number of aged patients at the Salpêtrière recorded as asthmatic, definite lesions of the heart and aorta, should have concluded that asthma, as an idiopathic malady, does not exist, being always symptomatic of diseases of the circulatory organs.

When we inquire into the conditions of cardiac dyspnoea, we find them to be: mitral stenosis and insufficiency, myocarditis and fatty degeneration of the heart-muscle, dilatation of the ventricles and aorta, from whatever cause, and uncompensated lesions of the valves of the aorta and pulmonary artery.

In the case of most of the above causes, the *modus agendi* is very simple; the dyspnoea is of mechanical origin, being the result of pulmonary stasis; the heart is unable to clear the capillaries in the sphere of the lesser circulation.

Most persons affected with mitral disease are short-breathed; when at rest they have little or no dyspnoea, but they immediately suffer for want of breath when they attempt any considerable exertion, as going up a flight of stairs, or ascending a hill. In the earliest stages of mitral insufficiency, the dyspnoea may be hardly noticed, except when the heart is severely taxed, as in the effort of running; in advanced stages, the difficult breathing becomes permanent on account of the constant pulmonary engorgement. There is nothing asthmatic about this, for the essential characteristic of asthma is the intermittent and paroxysmal character of the dyspnoea.

The difficult breathing attending aortic-regurgitant disease, aortitis, dilatation of the heart-cavities and aorta, fatty degeneration, etc., is generally paroxysmal in its nature, and the attacks come on in the night time rather than in the day. The explanation given by Professor Sée was formerly regarded as satisfactory: "The blood-stasis in the lungs, which is the first cause

of the oppression, manifests itself generally in the night time, because it is favored by declivity, that is, by the dorsal decubitus; to this first cause are added others which contribute much toward provoking the explosion of those attacks of respiratory distress which often present a formidable intensity; these purely mechanical causes are: distention of the stomach, the forcing upward of the diaphragm, which notably diminish the respiratory area already insufficient for haematoisis. Add, as accessory causes, bronchial catarrh and frequent concomitant emphysema, and you have the entire etiology of paroxysmal dyspnea linked to affections of the heart.¹

The dyspnea due to dilatation of the heart, according to Professor Sée, is almost always continuous, though there are paroxysmal exacerbations, and that due to fatty degeneration is *sui generis*, "presenting sometimes real paroxysms of distress and suffocation at the same time that careful examination of the lungs does not reveal any morbid signs; there is not the least acceleration of the breathing, or any apparent impediment to respiration."

Irritation of the cardiac and respiratory plexuses of nerves, as Peter, Rousseau, etc., teach, has been believed to have some share in the respiratory distress, and magical relief conferred by a hypodermic injection of morphine or other calmative, before even the pulmonary congestion or edema is mitigated, has been cited in confirmation of this doctrine.

Henri Huchard has, of late, written much and lucidly on the paroxysmal dyspnea of aortic regurgitation and aortitis. The dyspnea of aortitis is like that of mitral disease, at the first a dyspnea of effort, coming on during rapid walking, lifting, etc.; it is paroxysmal and often intense, rarely spontaneous. Later on in the disease, the attacks come on in the night time, often reproducing themselves with great regularity, so that the patient is obliged to pass the night in his arm-chair. Huchard regards this "aortic pseudo-asthma" as due to arterial hypertension which "augments by the recumbent posture and under the influence of sleep, as also by walking, and under the influence of movement." The cause of the dyspnea is "mechanical," as Professor Sée taught, but not in the same sense as he taught, for in Huchard's view, we have to do with "peripheral resistances," and "spasm" of the blood-vessels. If, says Huchard, distention of the stomach has anything to do with the paroxysmal dyspnea, abstinence from the evening meal or a very frugal repast ought to keep the patient free from his nocturnal attack; this is, however, sure to come, whether he eat little or much.

This dyspnea, Huchard affirms, is also of toxic origin. Experiments like the following seem to demonstrate this. He injects under the skin of a guinea-pig normal urine; death ensues in several days. He injects the same quantity of urine from a woman affected with arterio-sclerosis of the heart and aorta, and the guinea-pig scarcely suffers any detriment. This proves, he says, that the blood of his patient was poisoned

by the products of disassimilation which the kidneys, already impermeable by the fact of the aortitis and a commencing arterio-sclerosis, could but incompletely eliminate. These views, he urges, are not simply theoretical, they are confirmed by practice. In fact, blood-letting, purgatives, nitrite of amyl, nitro-glycerine, etc., which depress arterial tension, contribute in large measure to diminish the intensity of the attacks. But nothing works so well as an exclusive milk diet, which acts marvellously in combating these attacks of aortic dyspnoea, often keeping them completely in abeyance. Now milk diet, according to Huchard, acts in two ways and meets two indications: first, by the abundant diuresis which it provokes, the milk diminishes the arterial tension and promptly eliminates the toxic principles contained in the blood; then it acts by virtue of its very harmlessness and because it does not launch into the circulatory current, like other aliments, and meat in particular, materials which, not being completely eliminated, become rapidly toxic to the economy.²

MEDICAL NOTES.

— The following dispatches have been received by the United States Secretary of State from H. R. Newberry, *chargé d'affaires* at Madrid, under date of June 20-23, 1890:

"Sir: — It is difficult to say just the exact condition of things in the province of Valencia in regard to the cholera epidemic. This much is certain, that 120 deaths have occurred in the province of Valencia from cholera morbus, or Asiatic cholera, as the doctors are about evenly divided as to which it is. The inhabitants, such as are financially able, are leaving the country, and the government is sending physicians and medical supplies to the district in trouble. From conversation with my colleagues of the diplomatic corps, I am inclined to believe that the condition of affairs is not exaggerated, and that the disease is spreading gradually, as press dispatches keep reporting new cases, each time a little farther away from the original bed of disease. Three cases are unofficially reported in Madrid.

"At my own expense, I sent a man to the village of Puebla de Rugat, in the valley of Albaida. He has returned, and reports a sad condition of things. Out of a population of 1,500 people in the valley, there have been 127 deaths; 800 have fled to neighboring villages, and those remaining are in dire destitution, without money and food, and 200 of them sick. The authorities of the province are doing all they can, but they have no disinfectants, few physicians, and, with the extreme heat and deplorable condition of sanitary arrangements, the situation cannot help but become dangerous. . . .

"From private information, I know that there were 61 deaths in the village of Puebla de Rugat for the

¹ Vide Huchard, *Maladies du Cœur et des Vaisseaux*, Paris, 1889. Also, *La dyspnée chez les cardiaques*, in *Semaine Médicale*, April 13, 1890, p. 125.

² *Maladies du Cœur*, etc., 1883, p. 30.

twenty-four hours ending midnight June 19th, and 16 at Monticello, a village of 850 people. The Academy of Medicine has issued a bulletin stating that the disease is Asiatic cholera. . . .

"The authorities have prohibited anti-cholera vaccinations, as practiced by Dr. Ferran's system. The district of Gandhi is prohibited from exporting fruit and vegetables."

— Manor, a town of five hundred inhabitants in Westmoreland County, Pa., is strucken with a malignant type of typhoid fever. There are over two hundred cases in the town and the deaths have been four a day for the past two weeks. The cause of the scourge is attributed to the impurity of the water.

— Dr. John A. Wyeth, of New York, has promised to deliver the address before the Mississippi Valley Medical Association, at Louisville, Ky., October 8, 1890; and Dr. Frank Woodbury, of Philadelphia, will read a paper. A number of gentlemen prominent in medicine in the Mississippi Valley have promised to read papers and discuss subjects. Among these are Drs. Reamy and Whittaker of Cincinnati, Sutton of Pittsburgh, Corlett and Scott of Cleveland, Love of St. Louis, King of Kansas City, and many others.

— In a lecture on Syphilis, delivered before the Royal Academy of Medicine, Dublin, Mr. H. Fitzgibbon is reported to have read a quotation from Lancreaux's work on "Syphilis in Ancient Times and in the Middle Ages," found in Chinese medical writings so far back as 2637 B. C. This describes, it is said, what one cannot fail to recognize as a hard chancre, followed by all the phenomena which mark the course of a neglected case of syphilis. Commenting on this statement, the *Chinese Medical Missionary Journal* says this date seems to be somewhat wild. Wylie states that the oldest medical treatise extant is probably the "Hwang te soo wan," which there is reason to believe, he says, to have been written several centuries before Christ.

NEW YORK.

— At two o'clock on July 15th, the first water from the new Croton Aqueduct was permitted to enter the Central Park Reservoir. It was expected that the Mayor would be present, and turn the regulator at the gate-house; but he arrived a little too late to perform that function. After that the water flowed in from four small sluice-ways at the rate of 1,500,000 gallons per hour, in addition to the supply coming from the old aqueduct. At the meeting of the Aqueduct Commissioners on that day, the following resolution was adopted:

"Resolved, That, as our citizens enjoy to-day by the utilization of the new aqueduct, for the first time, the benefits of an undertaking which stands an unparalleled monument to engineering skill, and which in every way contributes to our city's health and welfare, the members of this commission warmly congratulate the public of the city of New York upon the virtual

fruition of an enterprise of such incalculable magnitude and merit."

In addition to the four pipes to Central Park, there are four other pipes, of the same capacity, from the 135th Street gate-house to various distributing points in the city; but water has not yet been let into them. Since the fresh supply of water is drawn from the same source as the old Croton Aqueduct, it will, of course, be understood that the completion of the new aqueduct does not imply an increased water-supply, but the means of bringing to the city more of the existing supply, and also the increased supply when new storage reservoirs now in contemplation shall have been finished and filled with water. The first of these new reservoirs will not be ready for storage until next spring. The most important of the new reservoirs is to be the one formed by the construction of the great Quaker Bridge Dam, and this has not yet been commenced.

— It has been decided not to contest the will of Mr. William J. Syms, which leaves \$350,000 to build and equip the fine operating theatre at Roosevelt Hospital. The will was probated last summer, and in April last a sister of the deceased began proceedings for the revocation of the will, on the ground that her brother was of unsound mind when he made it, and that he was under undue influence. The revocation proceeding has been abandoned, and there is now no obstacle to the carrying out of the will.

— In the Carroll case, in Brooklyn, in which the patient was supposed to have been poisoned by a dose of crystalline hyoscyamine put up by a druggist's clerk, in mistake for amorphous hyoscyamine, and in which the body was embalmed by an undertaker before an autopsy was made, the coroner's jury has rendered a verdict that the deceased came to his death from natural causes. The drug clerk was censured, however, for carelessness in filling the hyoscyamine prescription. At the inquest, Drs. Gustav Müller and R. G. Eccles were called as experts; and they testified that they had never heard or read of a case of hyoscyamine poisoning, and that the effect could not have been fatal whether the druggist had put up the crystalline or amorphous form of the drug.

— For some time past complaints have been made to Health Commissioner Griffin, of Brooklyn, about the persistence with which mothers of very young children have been besieged by manufacturers of infant foods and kindred preparations. Most of the complainants, it is said, have been physicians, some of whom said that they had been charged by their patients with betraying their circumstances to manufacturers. The physicians were, in consequence, led to suspect that some one connected with the Bureau of Vital Statistics was the guilty party; and an investigation by Commissioner Griffin, has resulted in the discovery that one of the clerks in this department had been communicating the name and address of every woman who became a mother, and had been paid by

the manufacturers referred to for the information thus conveyed. The practice was, of course, at once put a stop to.

Miscellany.

WOMEN'S SCHOLASTIC HONORS.

MISS FAWCETT's triumph in the mathematical tripos puts the crown on a long series of successes by women students at Cambridge. There have now been women "seniors" in all the important triposes (except law). Here is the list as we find it in *Science*:—Moral Science tripos: in 1880, Miss Jones was bracketed senior; in 1881, Miss Moberly was senior; and so in 1884 was Miss Hughes. Historical tripos: in 1886 Miss Rolleston (daughter of the late Oxford professor of zoölogy) was bracketed senior, and in 1887, Miss Blanche Paul was similarly placed. Mediæval and modern language tripos: here there have been four lady seniors. In 1886, two women and no men were placed in the first class. The women, who were placed in alphabetical order, were Miss Chamberlain and Miss Skeat (daughter of Professor Skeat). In 1887, Miss Harvey was senior; and 1888, Miss Tuke (whose father is well-known in connection with schemes of Irish emigration). Finally, there are the successes of Miss Ramsay in the classical tripos (1887), and of Miss Fawcett in the mathematical (1890). Of these eleven lady seniors, two came from Girton (Miss Jones and Miss Ramsay), the rest from Newnham. It is often asked what becomes of women students when they leave college. A few particulars about some of these lady seniors may therefore be added. Miss Ramsay is now Mrs. Montague Butler, the wife of the master of Trinity; Miss Moberly is head mistress of the Tunbridge Wells High School for Girls; Miss Hughes is head of a training-college at Cambridge; Miss Chamberlain is Instructor in German at Bryn Mawr College, Philadelphia; and Miss Jones is Moral Science Lecturer at Girton. Promptly to repair the apparent neglect of legal studies came the news of the success of women law-students at Paris, where Mlle. Belcesco, a Roumanian girl, has just taken her degree as *docteur en droit* after obtaining the highest place in the licentiates' examination. A French lady and two of Russian birth also did well. Mlle. Belcesco means to practise at the bar at Bucharest, confining herself to the cases of poor women who cannot pay counsel; her thesis for admission to the Paris faculty contained seven hundred pages, of which two hundred were, with an exercise of prudence on the part of the lady, not read. The fact that not Portia herself would be allowed to practise in England no doubt explains why women have not yet carried off the honors of the law tripos at Cambridge.

CHOLERA IN SPAIN.

DR. DE PIETRA SANTA presents a *coup d'œil* of the situation in Spain, in an article in *La Journal d'Hygiène*, July 3d, which is translated for the *Bulletin of the Marine-Hospital Service*, July 18th.

"A cholera epidemic has broken out in the province of Valencia, Spain. It showed itself on the 13th of May last at Puebla de Rugat, a village of 700 inhabitants. The disease cannot have been imported, the village being remote from the sea-board and having no

suspicious outside communication. It is undoubtedly a local epidemic, caused it is asserted, by the turning up of earth in the vicinity of a sewer. It will be remembered that in 1884 and 1886, Valencia was infected with cholera. The present epidemic is probably, therefore, a fresh outbreak of the former epidemic.

"From May 13th to June 15th one hundred persons were attacked; of these twenty died.

"At Montechelvo there were seven deaths out of fourteen cases. The inhabitants left the town and the disease died out. One case is reported at Valencia and one death at Albaida.

"The latest information received is that sanitary cordons have been placed around the infected localities, and that two-thirds of the population of these places have fled. It has been proposed to burn the earth infected by the sewers, an excellent means of disinfection when it can be effectively practised. The quarantine applied in the sea-ports of the provinces against outside communication would seem an unnecessarily stringent measure.

"The cholera epidemic of 1884 was especially severe in the province of Alicante. Valencia was visited that year by the epidemic, but only to the extent of 300 cases. In 1885, according to official statistics, there were more than 300,000 cases of cholera in Spain and more than 100,000 deaths, of which 21,612 occurred in the province of Valencia. It is also known that cholera was observed in Spain up to the beginning of the year 1886.

"The following sanitary facts may not be without importance in this connection:

"The city of Valencia has no system of cesspools. Private drains empty directly into immense sewers, constructed by the Moors hundreds of years ago, and which it is impossible to flush in a dry, warm country which has a slender water-supply. Many of the houses are ill-ventilated, ill-lighted, of bad construction, and with slight communication with the outer air. It was in such localities that the greatest number of cholera cases were observed during the epidemic of 1885.

"It is much to be desired that Spain should abandon the effete system of quarantine, which does more harm than good and which is equally opposed to sound scientific and humanitarian principles."

A CASE OF GREATLY PROLONGED GESTATION.

DR. RICHARD WILSON reports in the *University Medical Magazine* for July, 1890, a case of interest in the above connection:

"Mrs. M., aged twenty-nine years; married February 27, 1889; was regular all her life; saw her menses last on March 11, 1889. She says she felt motion in July. If we add 280 days to March 11th, we get December 16th, the day on which the child might be expected. On January 30, 1890, as the child was not yet born, Dr. G. P. Sargent of Bryn Mawr, the attending physician, called Dr. Atlee in consultation. On examination he found the 'child in the usual position; the back forward, the breech upward; the body inclined toward the right side of the belly, as the hand felt upward. In the vagina a hard head was felt. The neck of the womb was about half an inch in thickness, very soft, admitting the finger without much pressure.' On

February 2d Dr. Atlee saw the patient again, and there was no change in her condition, except that the neck of the womb was not thicker than a sheet of paper. As he heard nothing more of the case he supposed the labor had taken place.

"The following note was received by him from the attending physician, after the middle of March, under date of March 17, 1890:

"Mrs. M. was delivered of a boy at eight o'clock this evening. There is nothing unusual in the child's appearance. Weight about six or seven pounds. Delivery rather difficult, but without instruments. The funis was around the neck; large child, very active; both mother and child doing well."

"From March 11, 1889, the date of the last menstruation, to March 17, 1890, the date of the labor, there were 371 days, or six days more than a year. Supposing that her menses were suppressed on March 11th from some other cause than pregnancy, and that she had not become pregnant till the next menstrual period, which would be April 3, 1889 (adding twenty-three days, the usual time between the catamenia), then the duration of pregnancy (from April 3, 1889, to March 17, 1890) would be 348 days, or 11 months and 14 days, which is two and a half months beyond the usual term. But if this is the case, then she felt quickening at the third month, for, she says, she felt motion in July."

REPORTED MORTALITY FOR THE WEEK ENDING JULY 12, 1890.

Cities.	Estimated Population for 1890.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 4,070; under five years of age 2,191: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,340; consumption 351; acute lung diseases 192; diarrhoeal diseases 1,050; diphtheria and croup 94; typhoid fever 66; whooping-cough 43; measles 30; cerebro-spinal meningitis 23; scarlet fever 15; malarial fever 13; erysipelas 6.

From whooping-cough, New York 14, Philadelphia 9, Brooklyn 3, Boston 3, St. Louis, Baltimore and Nashville 2 each, Washington, Charleston, Fall River, Lawrence, Salem and Taunton, Worcester, Troy, Utica, New York 22; Baltimore 2; Philadelphia, Brooklyn and Lynn 1 each. From cerebro-spinal meningitis, St. Louis 8, Chicago 5, New York 4, Baltimore 3, Brooklyn, Worcester and Cincinnati 1 each. From scarlet fever, New York 5, St. Louis 3, Philadelphia and Baltimore 2 each, Chicago, Brooklyn and Lynn 1 each. From malarial fever, New York and Baltimore 4 each, Brooklyn 3, Nashville 2. From erysipelas, New York 3, Boston, Cincinnati and Lowell 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending June

28th, the death-rate was 16.9. Deaths reported 3,158: acute diseases of the respiratory organs (London) 206; measles 151; diarrhoeal diseases 102; whooping-cough 80; scarlet fever 44; diphtheria 42; fever 27.

The death-rates ranged from 10.6 in Bradford to 27.1 in Manchester; Birmingham 19.1, Bolton 18.9, Hull 14.6, Leeds 19.2, Leicester 14.5, Liverpool 18.6, London 15.9, Nottingham 11.3, Newcastle-on-Tyne 23.7, Sheffield 19.6, Sunderland 17.2.

In Edinburgh 17.3, Glasgow 23.6, Dublin 22.8.

In the twenty-eight greater towns of Scotland and Wales with an estimated population of 9,715,559, for the week ending July 5th, the death-rate was 17.4: deaths reported 3,236: acute diseases of the respiratory organs (London) 244; diarrhoea 150; measles 132; whooping-cough 92; scarlet fever 45; diphtheria 29; fever 16.

The death-rates ranged from 6.7 in Brighton to 23.3 in Manchester; Birmingham 16.9, Hull 14.6, Leeds 20.4, Leicester 16.6, Liverpool 16.7, London 17.5, Newcastle-on-Tyne 18.9, Nottingham 14.1, Sheffield 16.1.

In Edinburgh 14.6, Glasgow 24.5, Dublin 23.1.

The meteorological record for the week ending July 12, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.*		Rainfall. Duration Hrs. & Min. Amount in Inches.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 11, 1890, TO JULY 18, 1890.

By direction of the Secretary of War, leave of absence for three months, to take effect September 15, 1890, or as soon thereafter as his services can be spared, is granted Captain WILLIAM H. ARTHUR, assistant surgeon. Par. 1, S. O. 160, A. G. O., Washington, D. C., July 11, 1890.

By direction of the Secretary of War, the leave of absence, on surgeon's certificate of disability, granted Captain LOUIS M. MAUS, assistant surgeon, in Special Orders 4, January 6, 1890, from this office, is extended six months, on account of sickness. Par. 16, S. O. 160, A. G. O., Washington, D. C., July 11, 1890.

By direction of the Secretary of War, leave of absence for four months, on surgeon's certificate of disability, with permission to leave the Division of the Missouri, is granted Captain WILLIAM H. CORBUISER, assistant surgeon. Par. 4, S. O. 162, A. G. O., Washington, D. C., July 14, 1890.

Leave of absence for one month, to take effect the 30th instant, is granted Colonel CHARLES PAGE, assistant surgeon general, medical director of the department. Par. 3, S. O. 91, Department of the Missouri, St. Louis, Mo., July 14, 1890.

By direction of the Secretary of War, leave of absence for two months is granted Captain JOHN F. PHILLIPS, assistant surgeon. Par. 4, S. O. 164, Headquarters of the Army, A. G. O., Washington, D. C., July 16, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 19, 1890.

AUZALL, E. W., assistant surgeon, detached from U. S. S. "Galena" and wait orders.

ECKSTEIN, A. C., surgeon, granted leave of absence for month of August.

PENROSE, T. N., medical inspector, granted leave of absence for two weeks.

CABELL, A. G., passed assistant surgeon, granted leave of absence for the month of August.

ASHBRIDGE, RICHARD, passed assistant surgeon, granted one month's sick leave.

HEYL, T. C., surgeon, granted leave of absence for the month of August.

COOKE, GEO. H., medical inspector, detached from Navy Yard, League Island, and to the "Pensacola."

WHITE, C. H., medical inspector, detached from the "Pensacola," proceed home and wait orders.

HOCHLING, A. A., medical inspector, detached from Naval Hospital, and to League Island Navy Yard.

WELLS, H. M., medical inspector, detached from Museum of Hygiene and to Naval Hospital, Washington, D. C.

WHITEFIELD, JAMES M., assistant surgeon, ordered to U. S. S. "Ajax" and other Monitors.

WOOLVERTON, T., medical inspector, ordered to the U. S. S. "Philadelphia."

LOVERING, P. A., passed assistant surgeon, detached from the U. S. R. S. "Wabash" and to the U. S. S. "Philadelphia."

BAILEY, T. B., assistant surgeon, detached from the U. S. R. S. "St. Louis" and to the U. S. S. "Philadelphia."

WHITE, S. S., passed assistant surgeon, ordered to the Marine Rendezvous, San Francisco, Cal.

OBITUARY.

DANIEL WATERHOUSE NILES, M.D. M.M.S.S.

Dr. Daniel W. Niles died at his residence, in Worcester, Mass., July 17th, after a short illness, aged sixty-three years. He obtained his diploma at Dartmouth Medical School, and soon after settled in Worcester. The deceased was a veteran of the war, having enlisted in the 19th Massachusetts unattached. He was also a member of George H. Ward Post 10, Grand Army. He was a member of the Worcester District Medical Society and the Massachusetts Medical Society. About a dozen years ago he was city physician for one year.

Lippincott Co. 1890.

Clinical Diagnosis: The Bacteriological, Chemical and Microscopic Evidence of Disease. By D. Randolph v. Jaksch, Professor of Special Pathology and Therapeutics, and Director of the Medical Clinic in the German University of Prague. Translated from the Second German Edition. By James Cagney, M.A., M.D., Demonstrator of Anatomy at St. Mary's Hospital Medical School, etc. With an appendix by William Stirling, M.D., S. D. Brackenbury Professor of Physiology and Histology in the Owens College, Manchester, etc. With numerous illustrations (partly in colors). London: Charles Griffin & Co. Philadelphia: J. B. Lippincott Company. 1890.

Lecture.**INFLUENZA IN MASSACHUSETTS.¹**

BY GEORGE B. SHATTUCK, M.D., OF BOSTON.

WORCESTER COUNTY.

THIS county occupies the heart of the Commonwealth, and stretches across it from north to south. Though studded with manufacturing towns, it has a larger agricultural population proportionately than the counties previously considered. It may be regarded as a more homogeneous area than such counties as Barnstable or Bristol or Essex or Middlesex. I have tabulated twenty-seven returns from manufacturing companies, banks, etc., covering 11,405 employees.

The returns indicate that the epidemic affected Worcester County in general later than those counties we have already gone over to the east of it. The earliest first case is returned from Clinton, the Bigelow Carpet Works, December 16th, but the maximum week was the second week of January; and the Lancaster Mills, at the same place, reports the first case December 26th, with the same maximum week; West Upton reports a first case December 21st, but as a maximum week the third week in January; and a factory, in the contiguous town of Grafton, reports its first case January 9th, with the third week of January also as the maximum week. A shoe shop in Worcester reports a first case December 23d, and a maximum week January 4th to 11th; but the first case at the bank which reports was December 30th; and at the Loom Works, 500 employees, January 1st; a Worsted Company in Fitchburg reports its first case December 20th, but its maximum week the second week of January; and another company in Fitchburg dates its first case January 1st, and its maximum week the third week of January. Fourteen first cases are dated between January 1st and 10th, and the others in the last days of December. Eight returns give the third week of January as the maximum week, and fourteen the second week, one gives the fourth week.

The percentages of those attacked vary from 60% to 5%, and of those absent from work from 60% to "very few" — that is, less than 5%.

The Cotton Manufacturing Company of West Boylston, with 226 employees, reports "only one case, and that early in January." The average absence from work was between five and six days.

Medical Returns. — I have tabulated sixteen medical returns from thirteen different towns. The earliest first case, December 15th, is from Grafton, where the manufacturing company dated its first case January 9th, but the maximum week was the second week of January. Five returns — one each from Westborough, Worcester, Clinton, and two from Fitchburg — date the first cases December 20th; the other returns vary from December 22d to January 3d, this latter another return from Fitchburg. Ten returns name the second week of January as the maximum week, and four the third week.

The estimates of the percentages of population affected vary from 90% to 10%. Of two returns from Worcester, one says 90%, and one 50%; of three returns from Fitchburg, one says 65%, one 25%, one 10%; the medical examiner at Gardner, near Fitch-

burg, estimates 80% for his district. The average is 48%.

Sex. — Twelve reply males, and two females.

Other Diseases. — Twelve say that pneumonia was increased, one that pulmonary diseases were increased, and one that whooping cough was more fatal.

The next belt of the State to the westward may be regarded for our purposes as made up of three counties, Hampden, Hampshire and Franklin — in that order from south to north. The centre of these counties is traversed by the rich farming lands of the Connecticut River Valley, and the abundant streams from the hills are utilized for manufactures.

HAMPDEN COUNTY.

I have tabulated twelve returns from factories and banks in this county, employing between four and five thousand people. A Springfield Bank and a Holyoke Bank (the only banks sending returns) report "no sickness"; the Holyoke Blanket Company reports, "few sick at any time and did not interfere with work"; and the Germania Mills (Cotton), Holyoke, report "no loss of time from influenza"; but two thread companies at Holyoke report first cases December 24th and 26th, and the second week of January as the maximum week. A Firearms Manufacturing Company at Springfield, 213 employees, reports its first case January 1st, its maximum the second week of January; 10% affected, 5% absent an average of nine days.

No return from this county gives any earlier maximum week than the second week of January; but there is a report of a first case from near Palmer, December 18th, one from Ludlow a little farther west, December 20th, one from Chicopee — again, a little farther west — December 24th, but the other return from Chicopee gives January 1st as the first case.

There are some apparently more than usually accurate and interesting returns from a Duck Company at Palmer in the eastern part of the county, employing 325 hands. The first case in the dressing shop is reported December 30th, and the maximum week the second week in January; but the first case in the bleaching department did not appear until January 7th, and the maximum week in that department was the fourth week of January. In all the departments except the dressing, the first case was some time during the first week of January, and the maximum week was in seven departments the second, in one the third, and in one the fourth week of January. In the bleaching 87% were affected and 75% absent an average of five days; in the dyeing 80% were affected and 35% absent an average of six days; in the iron repair shop 75% were affected and absent seven days; in the weaving 66% were affected and absent an average of six days; in the other departments there were considerably less; and least, 25% with an average of four days, in the spinning.

Medical Returns. — I have tabulated thirteen medical returns from eight different towns in Hampden County. The dates given for first cases range all the way from October 6th in Monson, at the southeast extremity of the county, to December 26th at West Springfield and Holyoke in the northwest, and are so varied and unreliable that no conclusion can be based on them. One return from Palmer gives the date of the first case December 1st, but states that influenza did not become general until after Christmas. This

¹ Delivered before the Massachusetts Medical Society June 10, 1890. Concluded from page 77 of the Journal.

agrees with the factory returns and is probably the true interpretation of the medical returns; the maximum weeks given indicate the same thing; as do three different Holyoke returns dating first cases December 1st, 20th, 26th, but all giving the first week of January as the maximum week.

Seven returns name the second week of January as the maximum week, five the first week, one the third week. The percentages of affected vary from 75% to 20%, and the average of eleven returns is 44%. One practitioner profited, apparently, but little by the epidemic, as he reports that only one-fourth of 1% among his clients were affected.

Sex. — In this county eleven returns state that males were most affected. One return says: "especially out-door laborers"; one says: "male, those outdoors"; one says: "the careless, and those who tried to keep going every day about their business and work."

Other Diseases. — Eight returns state that pneumonia was increased and one that pulmonary diseases were; three (one from Springfield and two from Holyoke) report malarial complications; one return from Holyoke says it resembled "dengue."

Dr. A. F. Reed, of Holyoke, writes: "Bronchitis was common in most cases, but the most prominent influences seemed to be a union of rheumatic and malarial forces in a hybrid action, and in my experience quinine failed to give as good effects as salicin."

HAMPSHIRE COUNTY.

From this county I have tabulated thirteen returns from manufacturing companies, employing about 4,000 people. There is one return of a first case about "December 1st," one December 9th, one December 13th, one December 15th; but the maximum week in all of these returns is the second or third week in January. A factory in Northampton reports its first case January 1st and its maximum week immediately thereupon — the first week of January; but the first case at the Northampton Bank did not occur till January 5th. A silk company at Florence reports the first case December 9th; but a braid company at the same place reports its first case January 6th and its maximum week the second week of January; the same maximum week as that given by the silk company. From the silk mill 20% were affected and absent an average of eight days, and from the braid mill 25%, an average of four days. Eight returns give the first case between December 25th and January 7th; nine returns name the second week of January as the maximum week, and three the third week. The percentages of those absent from work vary from 60% to 5% and the time about six days.

Medical Returns. — I have tabulated eleven medical returns from seven different towns in Hampshire County. The dates of first cases vary from December 15th to January 1st. From Ware three returns date the first case December 20th, 27th, 28th. From Northampton three returns date the first case December 15th, 18th, 29th. One return names the first week of January as the maximum week, but all the others name the second week. One Northampton return gives 10%, one 25%, and one 75% as the proportion of the population attacked. One Ware return says 10%, one 33%, and one 40% as the proportion of the population affected. The Easthampton medical return says 60% of the factory employees, but 40%

of other population. The average of ten returns is 39%.

Sex. — These returns throw little light on sex. One return says, both sexes were most affected.

Other Diseases. — Six returns say pneumonia was increased, one specifying lobular pneumonia. One return from Northampton says: "there was no pneumonia, and all other diseases appeared to be abolished; there was one death from delirium." In regard to this Dr. Seymour, medical examiner, reports the following:

"A man, thirty-two years of age, had influenza at his home in Springfield. He got out of bed, dressed and came to his parent's home here in a state of delirium. He left their house at 2 A. M., and was found wandering about the streets by a policeman, who took him to the station house. There he remained in a wild delirium until 8 A. M., when, as he became silent, the keeper went to visit him and found him dead. I viewed the body and these were all the facts I could ascertain."

FRANKLIN COUNTY.

This county, the most northern of the three occupying the breadth of the State, is somewhat less thickly settled and less traversed by railroads than the two preceding. The manufacturing returns are scanty, and I have only tabulated one as apparently accurate.

The Russell Cutlery Company at Turner's Falls, at about the centre of the county on the Connecticut River, returns its first case January 6th, its maximum week the second of January, and 33% of its employees were affected and absent an average of 6 days.

Medical Returns. — I have tabulated five medical returns from five different towns. Three returns from the eastern part of the county, from Orange in the centre, Cooleyville at the south and Northfield at the north, give the first cases December 26th, January 1st and December 23d respectively, and the maximum weeks as the second for the first two, and the third week of January for the last respectively. The medical return for Turner's Falls reports the first case December 26th, the return for Shelburne Falls farther to the west reports the first case November 15th; both of these returns name the second week of January as the maximum.

The percentage of populations affected according to these five returns varies from 75% to 50%, the average is 66%.

Sex. — Three returns state that males, and one that females suffered the more.

Other Diseases. — Two returns state that pneumonia was increased.

BERKSHIRE COUNTY.

This county occupies the extreme western belt of the State from south to north. It also is less thickly settled than other counties, and communication between many townships is less immediate and direct than is the case in some of the other counties. There are, however, a good many manufactories within its borders.

I have tabulated returns from 16 factories, employing nearly 5,000 people. A company at Housatonic in the southern part of the county, and one at Adams in the northern part, return the earliest first cases, December 25th and December 30th respectively; the maximum week for the former being the first, and for

the latter the third week of January. Seven first cases are dated January 1st, two January 6th, one January 7th, one January 8th, one January 15th, one January 18th. One return names the first week of January as the maximum week, four the second week, nine the third week, and one the fourth week. No conclusions as to sex can be drawn from returns in this county. One return says "neither or both."

The percentages of the affected vary from 75% to 5% with an average of 45%, and of those absent from work from 50% to 3%, with an average of 22%, for an average of 5½ days.

The Arnold Print Works at North Adams reports "the epidemic did not cause any serious annoyance" among its 146 employees. This is striking, for of the two other manufacturers reporting from North Adams one had 50% of its employees absent, an average of six days, and the other 25%, an average of four days.

Medical Returns.—I have tabulated sixteen medical returns from nine different towns in Berkshire County. I am obliged to conclude that they are not of much value in determining the time when influenza assumed an epidemic character in this part of the State. The dates of first cases vary all the way from October 14th, at Montville, to January 8th, at Otis, neighboring towns in the southeastern corner of the county. At Montville the maximum week is reported to have been the third week of November. Evidently again a local outbreak. Two returns from North Adams each give December 15th as the date of the first case, the second week of January as the maximum, and 50% as the percentage of population attacked. Of three returns from Williamstown, next to North Adams, two date the first case January 1st, and one December 19th; the maximum week of one of the first two and of the last being the second week, the maximum week of the other being the third week of January. But the returns from Pittsfield are still more perplexing, of five returns, one dates the first case November 20th, one December 15th, one December 17th, one December 27th (this return mentions having seen a case November 27th), one January 5th, and the maximum weeks vary almost as much. From Sheffield, in the southwestern corner of the county, the first case is reported December 15th, but the maximum week did not arrive until the fourth week of January.

The percentage of population affected vary from 87% to 10%, with an average of 60%.

Sex.—Eight returns state that males, and three that females were more affected; one return says: "men complained the most, because it was their nature to, but women were really as sick."

Dr. S. C. Burton, Chairman Pittsfield Board of Health, writes January 26th: "In our House of Correction, of which I have medical charge, there were 105 prisoners; of these 96 males, 9 females. Ventilation to the male prisons by windows on the north and south side, to the female prison by windows on the east and west side. The windows in the male prison were open most of the time. The hall man was the first taken sick January 11th, the following day twenty-four men were sick, the next morning eight were too sick to go to the shop. January 14th twenty more were taken sick, and one or two a day afterwards, until the number reached fifty-six, all males; not a single case in the female prison."

Other Diseases.—Nine returns state pneumonia was increased; two that pulmonary diseases were increased; one that capillary bronchitis was increased.

SUMMARY OF GENERAL CONCLUSIONS.

Some of these returns are evidently quite accurate, and some mercantile returns and those of some public institutions, as well as a much smaller proportion of those of physicians, are based upon carefully kept records; other returns are only approximately correct; and still a third and not small class are mere guesses, which gain such value as they possess from the probability that the errors counterbalance each other.

In drawing conclusions, I have considered the date of maximum weeks of more importance than the dates of first cases.

The data furnished for Suffolk County by such sources as the Massachusetts and City Hospitals, the State Prison, the Post Office, the two large private banks quoted are probably pretty accurate; as are the returns from the Pacific Mills (Cotton and Prints), Lawrence, Essex County, 4,200 employees; and from the Pemberton Cotton Mills, at the same place; and from the Merrimack Mills (Cotton and Prints), Lowell, Middlesex County, 3,200 employees; and from the Bigelow Carpet Mill (Wools), Clinton, Worcester County, 1,050 employees; and from the Palmer Duck Company, Hampden County, 325 employees.

From these, collated with the mass of less evidently reliable returns which I have tabulated but not read, one may, perhaps, conclude that:

I. Influenza appeared first in epidemic form at Boston and its immediate vicinity; that the epidemic dates there from the middle of December, although there were sporadic cases earlier; that it culminated during the week between December 28th and January 4th; that it began to decline pretty rapidly from that date, although its after-effects still exhibit themselves in many forms.

II. That the epidemic was from ten days to two weeks later at the Island Counties (Nantucket and Dukes) than at Boston; that it was about a week later in Barnstable and Bristol Counties; and a few days later, perhaps, in Plymouth and distant parts of Norfolk Counties.

III. In the northern parts of Essex and Middlesex Counties, the epidemic was from five days to a week later than at Boston. Most of the towns reporting in these counties, especially in Bristol, Essex and Middlesex, are in constant, rapid and easy communication with Boston by frequent and crowded daily trains.

IV. It is difficult to explain why these counties were attacked later than Suffolk, and at the same time why Nantucket and Dukes were attacked still later than these counties. Neither a miasmatic wave, nor contagion, nor yet the two combined, as we understand them, cover all the observations.

V. The epidemic, apparently to some extent, radiated out from Boston as a first centre. That it behaved in the same way with regard to the surroundings of other centres of population, notwithstanding the suggestive report of the medical examiner at Ayer Junction, and notwithstanding similar propositions made elsewhere, I cannot satisfy myself from these returns. Except at a larger centre of population, it is not apparent why Boston should have been attacked before other points as far east on the coast; as a

centre of population, it is not apparent why it should have preceded New York; and neither geographically nor as a centre of population, why it should have anticipated London.

VI. With many puzzling local variations, backward and forward, and many contradictions, the returns indicate a later development as we proceed westward in the State, until in Berkshire County we find the epidemic developed fully two weeks later than in Suffolk; several days (four to five days) later than in Worcester; and about as much later than in the two Island counties to the extreme east.

VII. To judge from the returns of public institutions and of manufacturers, at least 40% of the adult population was seriously enough affected to have occupation interfered with. The medical returns, which necessarily are often guesses, agree with this. A considerably larger percentage probably was attacked.

VIII. The returns from two maritime counties indicate that exposure to atmospheric influences was an important factor, and men were more affected. On the other hand, where men and women were equally confined within doors by their work, as in mills, the women were both more seriously and more numerously affected.

IX. Returns from the McLean Asylum, the Massachusetts Hospital, the Boston Children's Hospital, the Tewksbury Almshouse, indicate that officers and nurses were more attacked than patients, an observation which corresponds with others elsewhere, here and in Europe.

X. In studying the returns of different mills one meets with singular cases of immunity from or predisposition to the epidemic. It is a curious anomaly, that one cotton mill should have less than half of one per cent. of its employees affected, and another 60%; that a silk mill should have 60% affected, a woollen mill in a contiguous township 15%, and a cotton mill in the next township 6%. The percentage of affected at several of the woollen mills is quite small, but this is not invariable, at others it was as high as 40%.

At print works there was a great variation in the percentages in different departments. From the Merrimac Manufacturing Company of Lowell, which kindly sent me special figures, I learn that the "departments having a hot, moist atmosphere were subject more severely to the effects of the disease, which was also more prevalent among the women and boys than among the men. The high percentage of the color shop (16%) was due more to the unhealthy nature of the room (which is cold and very draughty) than to the noxious influence of the chemical fumes. Such places as the print room (one case out of 55), indigo dye-house (no case out of 20), laboratory (no case out of 12), where the fumes from the drugs and chemicals are most conspicuous, were, comparatively speaking, free from any attack by the epidemic."

At the paper mills, where many operatives are exposed to a warm, moist atmosphere, the percentage of affected was, as a rule, low. How far this was accidental, or how far due to chloride of lime or other materials used in bleaching, may be queried. At the bleacheries of print works about 30% were attacked. At the bleaching room of the Palmer Duck Company 87% of the employees were attacked.

The Arnold Print Works at North Adams reports that the epidemic "did not cause serious annoyance"; whereas the Greylock Mills (woollen) at the same

place reports 75% attacked, and 50% absent from work an average of six days.

The Merrimac Print Works (all departments included), Lowell, had 18% affected; The Pacific Mills Print Works, Lawrence, had 29.50% affected; the American Print Works, Fall River, had 33% affected.

XI. Pneumonia was undoubtedly much increased in frequency during the influenza period all over the State. As to the character of the pneumonia—whether lobular or lobar; croupous, fibrinous or catarrhal; whether mistaken for capillary bronchitis—these returns give little information, and one must consult special papers—such as those read April 17, 1890, before the New York Academy of Medicine by Drs. F. C. Shattuck, E. G. Janeway and William Pepper.

XII. Some of the returns indicate that the presence of epidemic influenza was inimical to ("drove out") other forms of disease—as diphtheria and scarlet fever.

In the Connecticut River Valley, as might have been anticipated, it seems to have taken a malarial character.

XIII. To fit the mode of progression of the atmospheric disease wave—if the epidemic was dependent upon a miasmatic poison—with recorded observations in Europe and America, will tax the utmost ingenuity of the scientific meteorologist.

XIV. The epidemiologist will be quite as much perplexed if he seeks to explain all the phenomena by contagion.

I have endeavored to collate carefully returns as made, and to follow honestly where they seemed to lead without prejudice, and without regard to previous mental predispositions. When the returns seemed to offer no exit I have said so. Some errors have doubtless crept in, and some obvious lessons may have been overlooked. The picture, however, has not been varnished at the expense of truth.

The results are meagre enough, but they have yet to be compared with others before we quite despair of reaching some definite knowledge of epidemic influenza. The bacteriologist has failed to help us, and we must still struggle with the intricate problems presented without the aid of a specific micro-organism.

Under date of January 5, 1890, Hirsch, the distinguished Berlin epidemiologist, writes in answer to the editor of the *Deutsche Medicinische Wochenschrift*:

"I am persuaded that the present epidemic differs in no essential particular from those hitherto described. The great interest which the outbreak of this disease has excited is to be explained simply by the indifference of the great mass of the medical public to everything taught by history. . . .

"Whatever I had to say about influenza I have said in the second edition of my historico-geographical pathology, and nothing new has presented itself."

—The medical department of the University of Vermont at Burlington has adopted a requirement for a three years' course of study and lectures, instead of two, as formerly. And as a prerequisite, students, upon entering hereafter, will be required to pass an entrance examination, which shall be equivalent to the examination "required of such medical students by the board of regents of the University of the State of New York."

Original Articles.**THE NECESSITY FOR SOCIAL AND STATUTE RECOGNITION OF SYPHILIS.¹**

BY C. IRVING FISHER, M.D.,

Superintendent of the State Almshouse, Tewksbury, Mass.

The present is a time for the facing and discussing of social problems. The spirit of true philanthropy is abroad, and subjects, which a few years ago might not be mentioned in polite society, are to-day engaging the attention of able men and women throughout the land.

Crime and pauperism, which seemed to have little interest for the honest, law-abiding, self-supporting citizen, are now being studied from entirely new standpoints. The fact is being recognized that mental and moral blight have their basis in disordered physical conditions, and are often the result of immorality transmitted through lines of inheritance. "The fathers have eaten sour grapes, and the children's teeth are set on edge."

Students and lawmakers alike have ignored the fact that syphilis is present in every community, that it is an underlying factor of weakness in a large per cent. of the defective classes, that is, epileptics, feeble-minded, paupers, and low-grade criminals, and that the physical taint is the essential cause of the mental and moral degeneration.

That it is not confined to the lower strata of society is well known to every physician, for in the very highest social circles he meets and treats those who show unmistakable evidence of defection from the paths of moral rectitude; sins, perhaps, of long ago, but which no amount of repentance can eradicate from the bodies of helpless ones to whom its effects have been communicated.

Every other serious infectious disease has been fenced in with legal enactments. A man with leprosy, yellow fever, small-pox, etc., is by law shut out from contact with others, nor can the physician with impunity withhold from the proper civil authorities the fact that such diseases exist in his practice.

For every other disease requiring prolonged and specific treatment, numbers of hospitals have been established by both public and private charity, but I know of not one that is open to receive syphilitic patients as such. This is, perhaps, because the disease is the consequence of the violation of both divine and civil law. Public sentiment is not in sympathy with disregard of common morality, and is willing that the sufferer should reap the full harvest of his wrong doing. While this may be logical so far as the chief sinner is concerned, we seem to have lost sight of the fact that the penalty does not end with him. The sins of the parents visited upon the children run on countless lines of defect and pain, and the best forces of the community are being drawn upon for the care of these impotent ones in homes, hospitals, retreats and almshouses.

That these conditions have so long existed undisturbed, is due to the fact that the mass of thinking people, those who mould the best sentiment of the community, are unfamiliar with the disease. They scarcely know its name, and its wide-spread and disastrous prevalence are wholly unthought of. Enlight-

enment in these lines must come through the physicians. To them alone will the public lend a listening ear on such matters as these.

We have treated our patients, have discussed the various phases of disease with one another and in our exclusive and technical medical journals, but we have neglected golden opportunities to inform the public of its insidious nature and far-reaching destruction. Youth has been unprotected and parents unwatchful, because ignorant. Our work has been chiefly curative. It should be broadened, and become educational and preventive.

We who, in our daily walk, see on every hand what others do not see, the finger-touch of this monster evil, should "cry aloud and spare not," until our lawmakers are forced to give us such enactments as shall enable us to hold in check "this pestilence that walketh in darkness, this destruction that wasteth at noon-day."

"It is folly to exterminate diphtheria and small-pox and typhus, and let syphilis, the most prolific mother of evil of them all, send forth her brood of whelps to be the cause of more bodily and mental misery than all other shapes of human error combined." *

It is made obligatory on the part of physicians to report to the proper civil authority the existence in their practice of such contagious diseases as small-pox, diphtheria, etc., and persons so affected are strictly quarantined, and are not given their liberty until, in the opinion of the attending physicians, they are no longer liable to spread contagion. These maladies are in no way associated with dishonor or impurity. They may wipe out their victims from the face of the earth, but they leave no taint to be transmitted to descendants.

If the State has a right to take into its custody one citizen, because he has a disease which is dangerous to other members of the community, it has certainly the right to take another into its custody whose disease is not only dangerous to the present, but most woefully so to future generations, and which is developed and perpetuated by the voluntary violation of both divine and civil law. Yet syphilis, which in some of its manifestations is more loathsome than small-pox, which is an destructive, infectious and far-reaching as leprosy, which probably causes more deaths annually than all the epidemics which visit our land, is not recognized upon the statute book.

It does not appear as the cause of death upon the physician's certificate or books of statistics, because the practitioner does not always recognize it, or because out of kindly consideration for the friends of the deceased, he writes instead the name of the complicating trouble. "Rheumatism is written over the graves of strong men crippled in their prime; scrofula hides the secret sin of the parent stamped upon the slender frame of the invalid child; cancer is the foul lie buried with the wife, who has silently suffered the most excruciating agony which human flesh can endure." * If the impossible were possible, and we were able to gather the statistics regarding this disease, they would, I believe, be more appalling than any medical statistics ever presented.

"Grant that the individual may play what havoc he

¹ Read before the Massachusetts Medical Society, Suffolk District, Section for Clinical Medicine, Pathology and Hygiene, May 21, 1890.

* The quotations marked with an asterisk (*), on this page and the following one, are from the address entitled "Protection from Venereal Diseases," by Albert H. Gilson, Medical Director, U. S. N., before the American Public Health Association, at Nashville, Tenn., in 1879.

chooses with himself and his happiness, society has the right to demand that self indulgence shall bring no evil to a single other being than the transgressor." "No one questions the contagiousness of syphilis, or that its spread is the result of personal contact, and by what right any man or woman suffering with it may not only live in freedom, but actually solicit victims, it is difficult to understand." *

My point of observation has been among the low-grade criminal classes for four years and a half at the Deer Island Institutions, and for nearly seven years at the State Almshouse at Tewksbury. It is my fortune to-day to be caring for men and women, in the latter place, whom I began to care for more than nineteen years ago in the former place. Then they were active sneak-thieves, drunkards and prostitutes, now they are the "worthy poor" for whom the majority of good citizens think we "cannot do enough." The State Almshouse has a constant population of nearly 1,000 people. Last year, of 2,009 persons admitted to the institution, 1,721 were sent to the hospitals. Large experience in handling these people has led us, in our medical work, to make a thorough physical examination for evidences of syphilis, whatever the history given or symptoms complained of. We have found that many cases of rheumatism, paralysis, neuralgia, etc., respond to the orthodox remedies only, when they are combined with iodide of potash, or the green iodide of mercury.

During the year ending March 1, 1890, there were admitted to the hospital 1,058 men. Of these one had congenital syphilis; 54 had primary or secondary lesions well marked; while 496 had tertiary symptoms more or less active—a total of 551 syphilites, or more than 52% of the whole number admitted. The statistics from the female hospital are not given, because the specific examinations were not instituted there until later, and do not cover a whole year. I believe, however, that the above figures would not be materially changed were all the hospital departments included.

Next to intemperance, I hold that syphilis is the most important factor in the development and perpetuation of the dependent classes. There is not a tissue of the body which is exempt from its subtle and undermining influence. It renders the system more liable to other diseases, behind which it hides itself as under a mask. It is ever present as a factor of depression, weakening the will, lessening the vigor of manhood, and lowering the sense of responsibility. Whatever may be said of the curability of syphilis, it is practically incurable in the classes with whom I am in contact. They do not appreciate the nature of the trouble, nor will they, outside of a hospital, observe any of the conditions necessary for permanent relief. A large number go in and out, invariably improving while under medical observation, but degenerating rapidly when away and dependent upon their own resources. Finally, they come back to the almshouse with exhausted powers, to drag out a useless existence at public expense. Many of the children born in our hospitals show unmistakable evidence of syphilis which was not present in the mother, and which shows all too surely the character of those who beget illegitimate children. Pitiable indeed are these weak and sickly offspring of poisoned human bodies, and we can but cheerfully acquiesce in the interposition of Divine Providence which removes them from our sight and

care while the unequal struggle for existence has just begun. If these children survive the diseases of childhood and the neglect of ignorant or dissolute mothers, they, as a rule, go to swell the ever-increasing army of dependants which the State must carry as a dead weight, and at the maximum cost.

To protect the innocent and helpless, and to check this ever-increasing burden upon the State, legislative action must be secured. But legal enactments will be successful only as they are the outgrowth of public opinion. The mind and conscience of the community must be enlightened and awakened. We who must stand as educators need not only courage, but tact to engage the attention and active co-operation of the leaders of thought. Those of us who are connected with hospitals, or who hold intimate relations with the trustees of such institutions, have special opportunities for initiative work.

I believe the most rational approach to the object desired would be to secure the free admission of this disease to every municipal hospital and dispensary. In some of the larger cities special hospitals might be established. This would accomplish two things. (1) Some having the disease might be brought under treatment before their constitutions were so thoroughly undermined that they must be permanent dependants. (2) Statistics would be secured which could be used as educational factors, and so pave the way to such legislative enactments as the gravity of this disease demands.

Adequate legislation will meet with some obstacles, however. A law which may touch the pleasure of some who indulge in crime behind the screen of wealth and respectability; a law which may put to shame some in places of influence by bringing their secret sins to the light of day; a law which in its execution may bow with grief worthy families because some honored and esteemed one is shown to be untrue and impure—such are not easy of enactment.

But this, at least, may be secured,—that persons who have come under State control, whether as criminals they have been committed to some criminal institution, or have thrown themselves upon town, municipal or State bounty for support, if found to have syphilis, shall not be allowed to go out until the infectious stages are past, and they have been under medical observation and treatment for a specified time.

This would secure two things: (1) It would prevent not a small number of men and women from going out of the houses of industry, jails and almshouses, and communicating the disease to others. (2) It would send men and women out in a fair degree of health and strength, able to earn a living and properly care for themselves, which is not the case under existing law and custom. To my personal knowledge, within a year two syphilitic women have gone out from the State almshouse, and have married—one having the initial lesion. Again, I have learned of a woman under sentence in one of our State prisons. She was young, with a pretty face and pleasing manner. She attracted the notice and won the confidence of certain visitors. They interested themselves in her behalf. They could not see what the physician saw, the vile taint under the fair exterior. Mistaken philanthropy prevailed, and the woman was pardoned—virtually, though not nominally, released on the ground of good looks. She went out, and in a few weeks had communicated her disease to many persons.

Only day before yesterday there came to the almshouse, to visit her crippled, syphilitic child four years old, a well-dressed and, to all appearances, a healthy woman. She is a domestic in some home in this city. My conversation with her revealed the fact that the father of the child was a worthless fellow — she was not married — and that she had had a sore upon her lip, and later a sore mouth and throat, and that some physician had treated her, as she expressed it, for "the disease."

I would submit the following form of enactment, as suitable to be presented to our legislature for its consideration :

An Act to prevent the spread of syphilis by paupers and criminals.

Be it enacted. That any inmate of any criminal or public charitable institution, who has syphilis, shall at once be placed under medical treatment and observation; and such inmate shall not be discharged therefrom until three months after all infectious symptoms have disappeared.

This act shall not be construed to apply to any institution supported by private charity.

These suggestions include only those lines along which it seems practicable to act now. Some European governments have already established protective methods. New questions will arise here as public thought and feeling advance. As a step in educational work, why should it not be made obligatory upon the physician to place in the hands of his patient circulars regarding syphilis, such as are now furnished by boards of health relative to small-pox, diphtheria, scarlet fever, etc., telling the people how to care for the patient, and its dangers present and future?

We see this disease and its relations to the public welfare as no one else does or can. This work is a closed door to others. The key to the situation is in our hands. Every added knowledge brings an added duty and obligation.

How often have we treated our syphilitic patient, knowing well his condition and the disastrous results which must come in the marriage relation he was about to consummate; counting it "professional honor" to hold his dissolute secret, and sounding no word of warning to the healthy, honorable and innocent woman he was to marry — perhaps not even urging upon him the gravity of the situation, pointing out its far-reaching consequences, and appealing to his manhood to take the only honorable course, and spare the innocent and helpless?

How much longer shall we remain silent?

I believe the time will come when "professional honor" will have no part in holding the secret of one immoral, or even unfortunate, man or woman, when it is to bring disease, weakness, suffering and death to an unknown number of their offspring. The honorable majority of noble mothers and innocent children have rights which are not to be set aside by the dissolute minority.

The facts presented, however unpleasant, are facts none the less; and this disease must sooner or later receive the recognition which all other serious infectious diseases have received. The State will yet put its restraining hand upon the dissolute and vile, and exercise its legitimate power to preserve inviolate the manhood and womanhood of its citizens.

— The Mesopotamian epidemic of cholera has commenced to spread northwards towards the Black Sea.

REPORT ON DISEASES OF CHILDREN.

BY T. M. BOTCH, M.D.,
Assistant Professor of Diseases of Children, Harvard Medical School;
Physician to the Children's Hospital.

WINCKEL'S DISEASE.¹

AN endemic of acute haemoglobinuria in newly-born children was observed by Winckel, at Dresden, in 1879, the symptoms being cyanosis, icterus, hemorrhages from various organs, dark red discoloration of the renal pyramids, which contained streaks of haemoglobin, and fatty degeneration of the liver and other organs. Nineteen of the children died on an average within thirty-two hours after the beginning of the symptoms.

A few other cases have been reported by various observers, the last one being that one recently carefully studied by Hirst (*University Medical Magazine*, March 18, 1890) which occurred in the maternity pavilion of the University Hospital, Philadelphia. Labor was induced in the mother of the patient sixteen days before term, but was normal in other respects. The child, a female, appeared well-developed and was not asphyxiated. On the following day blisters were found on the legs and buttocks, probably the result of burning by hot-water cans. On the day succeeding this the body presented a brownish-green color, evidently a combination of cyanosis and icterus. The urine was of a dark red color, and contained methemoglobin. Inhalations of oxygen relieved the cyanosis to a considerable extent, but on the fifth day the child died.

Temperature was normal until the fourth day, when the thermometer registered 102° F.

On examination of the blood the red cells numbered 5,700,000. Three days later they equalled 3,400,000 the ratio of white to red being 1 : 13.5, and the hemoglobin eighty-nine per cent. Poikilocytosis was well-marked. Bacteriological studies of the blood revealed the presence of the micrococcus.

At the post-mortem examination the body was found emaciated, and with an icteric hue of the skin and mucous membranes. Several dark gangrenous-looking patches were seen, said to be the result of the contact of hot-water bottles. The lungs exhibited a large number of hemorrhagic infarcts of different sizes. The heart contained dark, fluid blood, and its muscle was somewhat degenerated. The cord and umbilicus were normal, as were the intestines and stomach. The liver seemed somewhat altered. The kidneys were cyanosed and injected. The mucous membrane of the bladder showed a number of pinpoint foci of ecchymosis. The spleen was large and congested. The mesenteric glands were enlarged and hard. Microscopic examination showed cocci in the liver, kidneys, spleen and lungs. There was some fatty degeneration of the heart muscle, and in the kidneys there was globular nephritis.

SECONDARY INFECTIONS IN SCARLET FEVER.²

The idea of a possible secondary infection has become too prevalent to allow it to pass without consideration. Chanin says that it results from penetration into the organism of a second microbe, which is added to and is distinct from the first. Before the idea of microbial infection was applied to the eruptive fevers the question had been raised whether the abnormal

¹ The American Journal of the Medical Sciences, April, 1890.

² Guinon: Rev. Mens. des Mal. de l'Enf., September, 1889 (Archives Pediatrics, April, 1890).

phenomena, appearing in the course of these diseases, was of the same nature as the primary disease, and whether they resulted from external or internal conditions; whether, in a word, they constituted a function of the primary disease or were the manifestations of another disease grafted upon the first. The discussion of this subject has, of course, a practical as well as a theoretical side. Bouchard, after studying the local manifestations in general diseases of the character under discussion, has demonstrated that the accidents and complications in these diseases are almost always new diseases, which are distinct from the original ones. The number and gravity of the complications occurring with scarlatina render it most suitable for the application of this theory. As a matter of fact, we do not as yet know the characters of the microbe of scarlatina, but we do know those of the micro-organisms which produce secondary infections in that disease. Klein, Crookshank and others have discovered micro-organisms which were supposed to be peculiar to scarlet fever, but their results are not entirely harmonious, and have not been entirely convincing. Lenhardt, Marie Raskin and BabéS, on the other hand, have studied the blood, the viscera, and the organs especially involved in the complications of scarlatina. In suppurative adenitis, Raskin found in seven cases, with or without diphtheria, a streptococcus which was constantly present. With tonsillar and pharyngeal ulcerations, Lenhardt found a thick layer of chains of streptococci, without the presence of gangrene,—that is, the streptococcus was evidently a secondary manifestation. In septicemia, occurring as a complication, absolute conclusions were not drawn. Raskin found a streptococcus and a small and oval micrococcus, but did not determine their nature nor their virulence. In the blood the streptococcus was rarely found. Raskin found it in only six cases out of twenty-three. Both Raskin and BabéS found the streptococcus, with other microbes, in connection with complicating pleurisy, pneumonia, pericarditis and endocarditis. It was believed that the bacteriology of the pericardium was identical with that of the pleura. In scarlatinal pyemia, investigators are agreed that the streptococcus is the most frequent cause, but other microbes are found at the same time in the same organ, or in the other viscera. In nephritis, an important point to be decided is, whether the microbe acts upon the kidney by itself or by the products which it secretes, and recent investigations tend to show that the former supposition is the correct one. Raskin has found and isolated in the kidney the streptococcus alone or united with a micrococcus, a diplococcus, or a bacillus, and they were also found in other organs. BabéS studied fourteen cases in which there were albuminuria and edema, and in thirteen the streptococcus, alone or associated with the pneumococcus of Talamon-Frankel was found. In scarlatinal rheumatism, three forms or varieties must be distinguished, a serous non-suppurative form, a serous suppurative form and a form in which suppuration occurs at the outset.

In the non-suppurative fluid of the synovial membrane Raskin found the streptococcus; in purulent arthritis the streptococcus may be found in great numbers. In the pus of otitis Raskin constantly found the streptococcus, and in the later stages of the disease it was associated with the staphylococcus aureus et staphylococcus albus. In diphtheria Raskin

found streptococci, diplococci, micrococci, and Loeffler, in addition to the streptococci, found also the Klebs-Loeffler bacilli.

From the foregoing it would appear that most of the complications in scarlatina are due, in all probability, to the action of a streptococcus, either isolated or associated with other microbes, and it has always presented the same character, with the exception that it varies in virulence. It is probably identical with the streptococcus pyogenes of Rosenbach, and Lenhardt thinks that it is modified in scarlatina by the primary infection. It is probably this organism which causes death in scarlatina either directly by septicemia or indirectly by nephritis. Secondary infection in this disease most frequently occurs by way of the pharynx, and the penetration of the microbes is favored by the loss of epithelium by the dilatation of the lymphatic channels, and by the recumbent position which the sick child assumes. The foregoing indicates antisepsis of the throat in all the pyrexias of childhood, but especially in scarlet fever, and before any complications occur, but caustic or irritant applications must always be avoided because of their destructive action upon epithelium.

INFANTILE HYSTERIA.³

According to Liebermeister, hysteria is the result of a functional disease of the gray matter of the brain. Hence it should be considered as a psychical disease, and not as a simple neurosis complicating psychical disorders. The view of Liebermeister is shared by other authors. They regard hysteria as essentially a psychical disease, because psychic symptoms are constantly manifest; because, in many cases, they are the first or perhaps the only symptoms which appear; because it is generally admitted that hypochondria, the analogue in the male of hysteria, is a psychosis; and because one frequently sees, as hysteria develops, phenomena which leave no uncertainty as to the psychic character of the disease. While in adults hysteria commonly shows a great complexity of symptoms, the hysterical phenomena in children are usually simple and clear.

The authors have treated, in the hospital at Basle, since 1874, hysterical children to the number of three boys and twenty-one girls, which may be divided into three groups. In the first group were the most simple forms of the disease, the morbid phenomena being merely certain modifications of character, and certain symptoms which differed little from the general disorders produced by anæmia. The second group included cases which were without violent attacks and without troubles of consciousness. In this class there was a tendency to localization of the disease, and the determination of such disorders as paresis, paralyis, contractures, localized anesthesia or hyperesthesia, precordial anxiety, aphonia, etc. In the third group were the cases which had convulsions with more or less loss of consciousness—the grand hysteria of Charcot. The following might be considered as its varieties: (1) attacks of hystero-epilepsy, or epileptiform hysteria; (2) chorea major, or rhythmic chorea; (3) spasmodus nutans; (4) tonic and clonic convulsions, usually atypical, occurring in paroxysms. With regard to etiology, it seems probable that predisposition has most to do with the origin of the disease, and this pre-

³ Hagenbach, Burchardt and Duvoisin: Rev. Mens. des Mal. de l'Enf., September, 1889 (Archives Pediatries, April, 1890).

disposition may be hereditary, whether congenital or acquired. The hereditary predisposition was observed in fifty-eight per cent. of the author's cases. In fifty per cent. of the cases there was hereditary tuberculosis. The most important predisposing conditions of an acquired character are anaemia and disorders of nutrition; all but two of the cases in the given series being anaemic. In several of the cases whooping-cough had exercised an unfavorable influence upon the constitution; in two there had been acute anterior polio-myelitis in early childhood. In eight cases fear and different local and general affections had exercised a decided influence. Of eight cases in which the first symptoms of hysteria were seen prior to the tenth year, there was hereditary predisposition in six. Of sixteen who did not become hysterical until after the tenth year, half of them had scarcely any hereditary antecedents.

If hysterical children are early submitted to medical treatment, improvement is usually observed within a short time; but the subsequent history may be unfavorable. Of twenty-two cases, fourteen suffered relapse within four years after their discharge from the hospital; and the others remained very anaemic. Of eleven who were more than seventeen years of age, and who had been more than five years out of the hospital, only one remained in good health. The others had attacks of migraine, palpitations, nervousness, psychical and corporeal weakness, hysterical psychoses, etc. In making a diagnosis of hysteria, epileptiform attacks and phenomena of simulation may cause much embarrassment. As to prognosis, Jolly and Briquet consider the disease a rebellious one, while Henoch and Weiss look upon it as devoid of gravity. It is sufficiently proven that it is subject to relapses and to psychical weaknesses. The treatment should aim, first, to combat the isolated symptoms of the disease; second, to act upon the general condition, and especially to relieve the anaemia.

ASPIRATION IN CHRONIC HYDROCEPHALUS.⁴

Aside from the dangers of local infection which may be easily avoided by rigorously following antisепtic principles, puncture of the lateral ventricles may lead to other complications which deserve to be taken into consideration. There is, on the one hand, the entrance of air into the cranial cavity, and, on the other hand, arterial hyperaemia of the brain which may result from too rapid depletion of the ventricle. To avoid these accidents the author recommends the exercise of manual compression upon the cranium during the puncture, and care that the flow of liquid from the ventricle should take place slowly and regularly, and these two conditions may be realized with such an aspirator syringe as was described in 1867 by Mosler.

With reference to the technique of puncture with the aspirator, it may be said that this can be best done through the anterior fontanel, and that the needle should be inserted away from the median line so as to avoid wounding the superior longitudinal sinus. Two cases in which this plan was tried by the author are described minutely. In the first, five punctures were made within six weeks, seven hundred and sixty grammes of serum being withdrawn. The improvement in the case was only transient. In the second case the punctures were made at longer intervals than the first, but the

results were not more satisfactory. The conclusion from this experience might be that the effect of these punctures is almost *nil*, the withdrawal of the serum being almost immediately followed by its reproduction. Nevertheless this treatment need not be entirely rejected, for there are several recorded cases in which a cure has been obtained; and though the effect of the punctures might be only transient, they would facilitate to a certain extent and for a certain period of time the development of the nervous centres, and may be practised without the least danger to the life of the children. When they are made with all necessary precautions they are not followed by any local inflammatory reaction.

For those cases in which phenomena of compression of the brain appear, with convulsions, etc., this mode of intervention is quite warrantable.

PARACENTESIS IN INTERNAL HYDROCEPHALUS.⁵

The author exhibited a case of acquired chronic internal hydrocephalus, for the relief of which he undertook paracentesis after trephining. The patient was a boy nearly five years old. He was seized with convulsions when three months old, and these attacks, which became very frequent, continued for nine months and then ceased. Three months after their commencement his head became enlarged. Every form of treatment had been tried, but without the least success.

Condition at the time of operation as follows: He was obviously imbecile; he could not talk, but smiled idiotically; he was totally blind; but the other special senses were not apparently affected. He had never walked or stood alone, but could easily move his body and extremities. His bowel and bladder sphincters were not controlled. He was extremely irritable and restless. He was fairly developed physically, but always of an ashy pallor. There was a very frequent rotary movement of the head, with slight retraction and grinding of the teeth.

The anterior fontanelle closed when he was eighteen months old, and the sutures had ossified at the usual time. The measurements of the head gave twelve and one-half inches from the glabella to inion; thirteen and three-quarters inches over the biauricular line; twenty inches around the fronto-occipital line. On the 4th of December, 1888, the author operated upon the case. Under the most careful antisepctic precautions, with a trephine about one centimetre in diameter, a button of bone was removed from over the coronal suture, about one and one-half inches to the right of the median line. A very delicate trocar was passed through the dural membrane into the brain-substance, downward, backward, and inward, to the depth of one and one-half inches, the object being to pierce the central cavity of the right lateral ventricle. About an ounce of a clear limpid fluid, closely resembling cerebrospinal fluid, was evacuated, and, as the trocar was withdrawn, a small quantity of the same kind of fluid escaped from the subdural space. For several days the same fluid continued to ooze from the puncture in the dura, and it was estimated that from four to eight ounces was thus discharged.

The case progressed satisfactorily. In two or three days he could stand alone, and he was gradually able to walk alone across the room, which he did in about three weeks. There was a partial restoration

⁴ Pfeiffer: Rev. Mens. des Mal. de l'Enf., December, 1888 (Archives Pediatrics, January, 1889).

⁵ Ayres: American Lancet, Detroit, 1869, xiii, 128 (Archives Pediatrics, February, 1869).

to sight. He became more attentive and seemed to understand better. He was less irritable and he slept well. The rotary movements of the head ceased. However, there was no development of speech, nor were the sphincters under any better control. The author believes that more fluid will have to be evacuated, as the patient is not quite so active now as some time after the tapping.

The chief difficulty lies in our inability to determine which cavity to evacuate. For instance, if the fluid resides in both cavities, and the normal openings between them, through the foramen of Majendie, and those behind the roots of the glosso-pharyngeal nerves be closed by inflammatory exudation, or the presence of a tumor, then to tap only the subdural space would remove the external pressure, and allow such an expansion of the internal fluid as would perhaps lacerate the brain-tissue. Or the same effect might be produced by evacuating only the ventricular fluid. This may have been the cause of death in some of the reported cases.

TWO CASES OF LOSS OF HEARING CONSEQUENT UPON MUMPS.⁶

The first case was that of a boy, five and a half years old; who had been subject to nasal catarrh, and frequently a discharge from both ears. One week after the onset of mumps, the hearing was suddenly lost, and there was marked giddiness, roaring in the ears, and pain in the back of the head. At the time of the report, six months later, the power of hearing was totally abolished, and the power of speech was nearly lost. The second case was that of a man thirty-five years of age. At twelve years, during an attack of mumps, the hearing was entirely lost and never had been regained. The tympanic membrane and Eustachian tubes were normal.

The author believes that the lesions in both cases was in the labyrinth, but the nature of the pathological process is somewhat uncertain.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT, SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

REGULAR Meeting, Wednesday, May 21, 1890, DR. A. L. MASON in the chair.

DR. C. IRVING FISHER, Superintendent of the State Almshouse at Tewksbury, Mass., read a paper on

THE NECESSITY OF SOCIAL AND STATUTE RECOGNITION OF SYPHILIS.¹

DR. F. B. GREENOUGH: I shall have very few words to say on this very interesting subject of Dr. Fisher's paper. It seems to me it is one difficult to discuss beyond endorsing the very vivid picture he has painted of the prevalence of syphilis and the necessity for doing something, and the best we can under the circumstances. The subject, of course, is a very impor-

¹ See page 101 of the Journal.

² Barr: Glasgow Medical Journal, June, 1889 (Archives Pediatrics, March, 1890).

tant one owing to the prevalence of syphilis, its liability to spread by contagion and more than that to be handed down from parent to offspring. Unfortunately this social evil in the same way as other social evils, notably prostitution, is one in which the great difficulty which society finds in handling it, is that it is much easier to point out the evil and direct attention to it, than it is to formulate or lay down any practical means of overcoming it. Nevertheless the fact that we are not able to overcome all or even the greater part of these difficulties is no reason why we should not, on the contrary it is every reason why we should, devote ourselves to remedying them as far as we can; and it seems to me that the suggested legislative action that Dr. Fisher has advocated is certainly a most excellent opening wedge for this very important purpose.

He has given us a most vivid, realistic and true picture of the prevalence of the disease. Of course, the cases he sees do not represent the proportion in the community any more than the large proportion that I see in the dispensary would do the same. Nevertheless in the community generally, as all general practitioners and more especially those members of the profession who see more or less of special practice are aware, the disease is very prevalent and I think without question is becoming more so of late years, although that is thing that is difficult to prove.

One point to which Dr. Fisher referred interested me especially, namely, the necessity of hospital accommodations for cases of this sort. You commonly hear that there is no hospital accommodation for syphilitic patients. This is by no means true as the large number that Dr. Fisher has taken care of at the almshouse proves, and a large number come to the dispensary for treatment. Beyond these a certain number do get into the hospitals but theoretically they have no business there. The truth is, however, that according to the rules of the large hospitals, syphilitic patients are not admitted; and that for a poor person suffering from syphilis to get hospital treatment, it is necessary for him either to be sent to Tewksbury or go down to the Island, which latter he can't do unless he has a residence in Boston. The case often comes up at the dispensary, of men who are apparently respectable, who have no money and don't know what to do or where to go, and it is often impossible for me to suggest anything to them. Those who are lucky enough to get to Tewksbury or on the Island get well treated. It would be important to have large hospitals or other hospitals in the city and large centres where such patients could be properly taken care of.

I agree with Dr. Fisher entirely that it would not be well to have a hospital as a simple syphilitic hospital, or if it were so, not to call it such, as undoubtedly it would act very strongly against its usefulness and naturally we can't expect a patient if he has been unfortunate or even wicked in acquiring syphilis to have it given to the world if it can be avoided, and that would prevent exactly what we wish to accomplish.

Assuming the great advantages of hospital treatment, what are the reasons why it has not been heretofore included amongst the large and successful charities in which diseases of other kinds in our poor people have been treated? I think the first, perhaps, is the fact that syphilis has in connection with one other social evil, namely, prostitution, been treated here simply by being ignored, that is, the community, legislators, etc., wish to ignore it and that is a very poor way to treat

it. In addition to this reason, which is no reason at all, there is a feeling, undoubtedly in the community, that a person who has syphilis has it as a result of immorality, of sin, and consequently ought not to receive the benefits which the respectable poor should have. As to the Christianity or logic of that I have nothing to say, but even admitting that there is something in it there are many cases of syphilis in which that does not come in at all. Amongst the female patients who come to the service at the dispensary I am quite sure that over fifty per cent., are suffering from syphilis without any fault of theirs at all, simply as a result of being wives of men who have sinned and who have acquired the disease. Certainly these women instead of being punished on account of their misfortune, ought to receive extra care and attention. Apart from that there are not a small number of cases of syphilis in which the disease was acquired without any fault, by contact other than that of sexual intercourse. It is not at all infrequent, and my only wonder is that we do not more often see primary lesions on the lip, where we get a history of drinking out of the same tumbler or smoking the same pipe, which somebody drank out of or smoked, who had the contagious lesions in the mouth. The mucous patches about the mouth being so very contagious, and acts of kissing, drinking out of the same tumbler, smoking the same pipe being so common, my only wonder is that more people are not infected in that way. Probably all of you, gentlemen, certainly all of you who have seen much of special practice, are aware of the fact that many physicians have been inoculated, certainly without sin, in the practice of their profession.

It might also be urged against admitting syphilitic patients into the hospital, that, being a contagious disease, it would be dangerous for other patients. At the present day when so many diseases are claimed to be contagious, and when we have wards for almost all contagious diseases, that would be a reason hardly necessary to mention, but undoubtedly that has been considered by trustees, etc., in excluding it.

These being some of the reasons that probably have been urged against giving syphilitic patients hospital treatment what, on the other hand, can we urge for the necessity of so doing?

In the first place — *for the sake of the patient* — I would put that first, although perhaps, it ought to come last. We all know that syphilis, especially in its early stages, is extremely amenable to proper treatment. Patients who are put under proper treatment will, in a comparatively short space of time, be free from contagion and if proper treatment is continued sufficiently long I have no question that at the present day a great number of patients do throw it off entirely, whereas after having such treatment as a poor person would receive outside of a hospital, the chance of their becoming burdens to themselves and to society, as Dr. Fisher has so graphically described, is almost certain.

Another consideration is the removal of such persons from the possibility of communicating the disease to other people. Dr. Fisher has treated this so thoroughly that I will only endorse what he has said. I would mention in addition to the danger of contagion from sexual contact the danger of perfectly innocent contagion from the lips, etc.

The proper treatment during the early stages, such as poor patients would get in a hospital, would be of the greatest importance in diminishing the chance of

handing it down to posterity, which is, of course, one of the important ways in which the disease is spread.

One of the most urgent reasons for hospital treatment, I think, is the ability that medical students and practitioners would have of seeing cases of this sort, and I think if there is any disease in which clinical opportunities for seeing, watching and observing cases is important, it is in *syphilis*. There is no question about that. Syphilis, spread abroad as it is, liable to crop out in all classes of the community, luckily, in many cases, presents appearances on the mucous membranes and skin, which to the skilled eye are distinctive. The eruption is seen, and you realize at once that it is syphilis. Physicians often come to me with a case, and say: "I can get no history." You see something before you, and, no matter what the history, you know it is syphilis as surely as you know that a horse is a horse. That power can only be acquired by *seeing cases*, and if the student does *not* see cases, and the practitioner, in the early part of his practice, does not see cases, they can't recognize it; and one of the most important things in acting as a check to the spread of the disease is its early recognition.

One other thing I will refer to, and that is the expense, and the crowded condition of our hospitals, and the desire not to admit patients who will not be very much benefited thereby; but it seems to me that syphilis is just exactly one of those diseases which would be benefited by a stay in the hospital, more so than cases of cancer, phthisis, or, in fact, many diseases. If these patients could be for a few months or even weeks in the hospital, they would really derive more good for themselves, and secondarily for the community, than in a great many other diseases that are admitted without any question.

DR. J. C. WHITE: Dr. Greenough has so completely covered all the points which would occur to any subsequent speaker to allude to, that nothing remains to be said, I think, by myself of any great importance. I want, however, to insist upon what I consider to be a very important, because false, position which this disease holds in the community: that is the popular idea that there is a moral stigma necessarily connected with syphilis; that it is a subject which should not be spoken of publicly, and should not be treated in our hospitals. I think that the community needs to be alive to this fact that syphilis is no more a venereal affection than some other infectious diseases, no more so necessarily than leprosy, that it is not in itself a venereal disease at all, that it has had that secondary character engrafted upon it simply by our customs of living. No doubt syphilis is, in the great majority of cases, conveyed from one person to another by sexual contact, but, as Dr. Greenough has stated, it prevails in other classes of the community through inherited tendencies, through contact with implements used in trade, the social customs of eating and drinking, and not by any means infrequently through professional handling of patients. I have kept a list of physicians whom I have seen directly or indirectly as patients, with syphilis thus acquired in the past few years, and their number is astonishingly large. The mortality in our own profession from such forms of syphilis is not inconsiderable in the last ten years. If we go into communities of a lower civilization we find that syphilis is often conveyed in other than venereal ways; and I think that syphilis should be regarded as leprosy is regarded by public enact-

ment and by the community. If a leper comes to this port, the newspapers are full of it. He is looked at through a glass case; nobody wants to touch him or go on the same steamer with him. It is no more dangerous for a leper to come to Boston, to any hospital in this city, to this room, than a case of syphilis; and there is no more danger of infection; it is not in any way so dangerous to the community, as a whole, as is a case of syphilis, and the public should be made to understand this. If we go to a nation where the social habits are different, we see how syphilis may take on the course of infection and spread as some other non-venereal diseases do. If we go to a virgin soil, as leprosy went to the Sandwich Islands, there, owing to the peculiar customs, we find leprosy spreading as an endemic, and affecting a very large percentage of the people. So syphilis, in the history of these Islands, had a similar course. Of course the dissolute manners of those people made this all the more easily communicable from one person to another; but the same habits of living in other ways, the dipping of the finger into the dish of poi, passing around the same social glass in a large company, the use of the pipe passed from one mouth to another, the same intimate habits of living in close contact, and sleeping in close contact, acted precisely to spread syphilis for the first time among these Islanders, as they later acted to spread leprosy among them. It is essential that people should understand that syphilis and leprosy are exactly on the same plane; that one is no more necessarily immoral than the other, that one is just as dangerous as the other, and that syphilis is far more dangerous in this community, stalking, as it does, without any means of restraining it, than leprosy is at present in the United States, or is likely to be.

Now the only way to eradicate syphilis is to treat it, and to treat it in its beginning. Next, to isolate it as far as possible by such enactments, which may work a little way, as Dr. Fisher has here presented to-night. The public should understand that syphilis is dangerous to the individual. It is dangerous because it produces the gravest results to him often in spite of treatment, for it is a most insidious affection; that it is, at times, with great difficulty recognized, except by experts; that it is of the utmost importance that medical men should, as Dr. Greenough has stated, have every opportunity to learn to recognize it, far more than many other affections to which they have so much of their time devoted; that trustees of hospitals and managers of medical schools do not do their whole duty, if they continue to exercise the present narrow selection of cases for admission to hospitals. They say, virtually, a student shall be allowed in this hospital to recognize a case of fracture or rheumatism, which is confined to that individual in one case alone, but he shall *not* have the opportunity of learning to recognize one of the most dangerous diseases which exists in this community. They say to the medical students of New England: "You shall not have that opportunity," and they should be held responsible for it. It should be known to them, as to the community, that syphilis is dangerous, not only to the individual, but dangerous to his family immediately living with him, dangerous to his descendants, dangerous to the community at large.

DR. DURGIN: There is very little that I can add to what has already been said. The paper is a very pleasing one, and the remarks have covered the ground very completely. I think that it is a fact that the

community is very ignorant as to the extent and nature of syphilis. In the first place, those who recognize the disease and know anything about it say very little; the cases are never reported. They are treated quietly, not taken into the hospitals, because nobody wants to come in contact with them, and therefore the community is left ignorant both as to its extent and dangers. It has been wisely said by Dr. White, that this disease is more dangerous than leprosy. It seems to me so, and for one reason which has not been mentioned, that is, that a case of leprosy frightens every one, and any family in which a case of leprosy occurs is made fully aware of its dangers, and will take good care in handling it, but with syphilis I do not think that this is the case. In most families syphilis might occur, and the rest of the family remain perfectly ignorant of the fact. When they become aware of it, they don't understand the contagious nature of it, and the exposure is very much greater than in a case of leprosy. The fact that it is not taken into the hospitals is to be regretted. It seems to me that cases of syphilis could be treated in any of our hospitals without danger to the other inmates. With the present knowledge in the care of contagious diseases, it seems to me that this one might be treated as safely as any of the others, the danger not being through the atmosphere, but requiring contact. It seems to me that clothing, etc., which might become infected, could be so completely cared for as to avoid any spread of the disease. I don't see why syphilis should not be treated in any of our public hospitals. Not many years ago, a case of syphilis was reported to the Board of Health, and we were appealed to, to take charge of the case, which seemed to be a very bad one, and seemed to endanger other inmates of the house. We had determined to take charge of this case and send it to a hospital, but, on examining it, it did not prove to be one of syphilis. There have been two such cases within a few years. I felt disappointed at the time in not finding them to be cases of syphilis, hoping that we might take the initiative, and see how far the act would be approved by the public. I am very glad that this movement has started in the profession, and I am inclined to think that if the matter should be properly managed before a committee of the legislature, that favorable action might be secured.

DR. WIGGLESWORTH said: Specialization is the gauge of progress in civilization. The savage relied upon himself for everything and the results were of the rudest description. To-day it takes eleven men to make a pin, but how perfect the finished product!

(1) The civilization of to-day demands special hospitals or, where that is impossible, special wards in general hospitals, for each special division of medical practice. Some exist already, but professional jealousy and ignorance of the amount already accomplished in the direction of the treatment of diseases of the skin, have thus far prevented dermatological hospitals or even wards. Another drawback has been the gross ignorance which, founding its classification upon a physical localization rather than upon a pathological basis, lumped together the most dissimilar morbid processes under the general head of "venereal" diseases; and, of course, a ward could hardly be devoted to a branch of medicine and cases of general, external, constitutional, chronic syphilitic dermatitis and their sequelæ, and at the same time to a branch of special surgery with its cases of internal, non-constitutional, acutely

inflammatory maladies. We cannot base a medical classification upon the fact of the greater relative frequency of one of the many means of infection by different poisons. The poisons remain as distinct as the Kohinoor and a koprolite though both should be carried upon the same charger. I have known the kick of a horse to produce deafness in one case and a broken leg in another. We would hardly class these conditions together medically on account of their origin. The status of our profession to-day demands, I repeat, special hospitals or wards, at least, for both diseases of the skin and for genito-urinary surgery, the two to be kept most thoroughly distinct, if only as a means of overthrowing old superstitions and errors.

(2) Again; the civic dignity of our municipality demands that she shall not be left in the extreme rear of scientific and humanitarian progress. Boston is to-day perhaps, the only civilized city of any importance, absolutely without special hospitals or wards for skin diseases. As long ago as 1873 I had the curiosity to look up the condition of Italian cities in this respect. I found that Florence (population 120,000) and Rome (population 210,000) had special professorships and clinics for diseases of the skin and syphilis. Bologna (population 90,000), Naples (500,000), Palermo (population 170,000), Turin (population 185,000) and others, had each a professor and a clinic for these departments. According to sanitary regulations, enacted since the unification of Italy, the largest cities must possess special hospitals (syphilicoma), smaller ones special wards in their general hospitals. *By law no impunius syphilitic patient could be refused admittance.* I selected Italy because Germany and France were well-known to pay almost excessive attention to these branches. Now remember this was the condition of small Italian cities nearly twenty years ago. What is the condition to-day of the "Modern Athens of America" with its nearly half a million inhabitants and after the example set by Europe for, at least, a quarter of a century? Not one hospital, nor even one ward, for skin diseases and syphilis! and like the rude Carthaginian boor it even shuts its hospital doors against the houseless stranger and sends him away to disseminate his infection throughout the community. Five years ago I took occasion to investigate the condition of other American cities in this respect. New York had a skin and cancer hospital, and two wards for skin diseases at the Charity Hospital, to say nothing of the wards for syphilis on Blackwell's Island. Philadelphia had a ward for skin diseases at the University Hospital, one at the Philadelphia Polyclinic, and one at the City Hospital. Chicago took cases into both the Presbyterian and the Michael Reese Hospitals.

(3) And now in conclusion: — the object of hospitals, I take it, is the relief of suffering, the protection of the community, and the instruction of the profession. For all these reasons special wards and even hospitals are demanded. Why should small-pox, a comparatively slight disease, running a speedy course, preventable by vaccination or, if present, easily recognized and avoided, arrogate to itself an exclusive domicile; and the great pox be left absolutely houseless to run a course of, at least, three years, a course of steadily increasing intensity and yet, as a rule, unsuspected by those exposed to its infection? Why should leprosy have its special hospitals and these very hospitals even be isolated from inhabited places, and syphilis receive no attention although a precisely similar disease, due,

like leprosy, to a bacillus, propagated in the same way by inoculation, but with vastly greater ease, and entailing results exactly as bad in all respects as those of leprosy? The only difference is that syphilis is curable and, as a rule, easily cured, with *proper* treatment. All the more reason, therefore, for giving to the patient this proper treatment! Syphilis is more readily communicated than leprosy. All the more reason for protecting the community by the seclusion of the infected patient! Syphilis is furthermore one of the easiest diseases to cure, with *proper* treatment on the part of the physician. All the more reason for giving both physicians and students the opportunity to learn in what this *proper* treatment consists, as well as to make a right diagnosis, upon which so often depends the moral and mental, as well as the physical welfare, not merely of the patient, but of his whole family. No! the question is not, "Ought we have special wards and hospitals?" but, How is it possible that hospital boards have so long dared to delay to furnish them? Their injustice is explained, not excused, by ignorance. But what shall be said of their medical advisers? Has not the community a right to demand whether it is merely ignorance upon our part or whether there may not be a deeper motive; whether it is a lethargic indifference to the rights of humanity and to scientific progress or an active interest in means for our own personal advantage?

To avoid the possibility of such a reproach, it behooves us, as physicians, to strengthen by all means in our power every influence which can be brought to bear upon those in whose hands it lies to establish special hospitals or wards. According to the last report of the Trustees of the Boston City Hospital, "Suggestions and recommendations have been made from time to time, to the trustees, by the medical and surgical staff, that wards be set aside for the exclusive treatment of patients by the special departments. Such recommendations seem to be in accordance with the tendencies of the times and the progress of medical science. Diseases of the eye, of the skin, of the throat, of women, can undoubtedly be better treated in wards especially adapted for their purposes; and the trustees would gladly assist in such further classifications and special treatment, were there wards enough. . . . The death-rate from 'contagious' diseases will remain inexcessably high, in comparison with other large communities, especially abroad, until our community shall better appreciate what is done elsewhere, better comprehend the dangers of contact, and until the city is able and willing to pay for the best means and methods." The people have the power; we must educate them to use that power properly.

DR. MCCOLLUM: There has been so much said, and so well said, that I do not think I can add anything to the remarks that have been made. I was very much struck by one of Dr. Fisher's remarks with reference to the discharge of patients from the various institutions. It frequently happens that men or women who are suffering from syphilis will be discharged from the jail. There is no power to control it. They are advised to go to the dispensary or to Tewksbury. In some cases they do so; in other cases they do not. Of course, this question is an important one, and it is a question which the profession should take hold of in earnest. Much can be done by proper legislation; but I think even more can be done by the efforts of individual physicians in educating their patients up to the

fact that syphilis is so contagious. A comparatively small number of patients have any idea of the contagiousness of syphilis. They should also be instructed as to the importance of continuing treatment a very long time. The majority of patients stop treatment too early, and, as a result, are not properly treated; and they do not resume treatment until something new manifests itself. Hence the importance of a department in our hospitals for skin diseases and for syphilis is very great.

DR. P. C. KNAPP: I want to add just a word with reference to the comparison which has been made here a number of times between leprosy and syphilis. There is one point which, it seems to me, has been forgotten, that is, that when leprosy attacks a patient, it kills him eventually; when syphilis attacks a patient, the patient is cured in a few years, and then, five or ten or twenty-five years later, he or she comes down with tabes, with an attack of hemiplegia, or with general paralysis or some other of the late nervous manifestations, which, if not due directly to syphilis, are vastly more frequent in syphilitic subjects than in persons who have never had syphilis. That, it seems to me, is a thing that should be borne in mind, and should emphasize what the dermatologists have had to say tonight in regard to the necessity for some effort to check the spread of syphilis.

DR. J. C. WHITE made the following motion :

Voted, That the Section of Clinical Medicine, of the Suffolk District Medical Society, earnestly asks the attention of the managers of the Massachusetts General and City Hospitals to the subject of hospital accommodation for syphilitic patients, and expresses its conviction of the pressing importance of such provision in the institutions under their charge.

The motion was passed unanimously, and the Secretary was directed to transmit the vote of the Society to the Trustees of the Massachusetts General and Boston City Hospitals.

DR. C. IRVING FISHER presented the following suggestion for legislative consideration :

An Act to prevent the spread of syphilis by criminals and paupers.

Be it enacted, etc., as follows: That any inmate of any criminal or public charitable institution, who has syphilis, shall at once be placed under medical observation and treatment, and shall not be discharged therefrom until three months after all infectious symptoms have disappeared.

This Act shall not be construed to apply to any institution supported by private charity.

The vote of the meeting was taken, and it was in entire approval of the above suggestion, and a committee of three was appointed to take action thereon. The Chairman named Drs. C. Irving Fisher, J. C. White and F. B. Greenough as that committee.

Adjourned at 10.30 o'clock.

— A preliminary meeting of the incorporators of the proposed Rush Hospital for consumptives in Philadelphia, has been held. The list includes many of the well-known names in Philadelphia medical circles. A location in West Philadelphia is under consideration.

— A moderate epidemic of typhoid fever has occurred at Princeton, N. J., which, if we are to believe press reports, has been traced, like the recent one at Waterbury, Conn., to a milk supply.

AMERICAN OTOLOGICAL SOCIETY.

TWENTY-THIRD Annual Meeting, held at Hotel Kaaterskill, N. Y., July 15, 1890.

MORNING SESSION.

President DR. OREN D. POMEROY, of New York, in the chair.

The first paper was entitled

MASTOID' SCLEROSIS, AS ILLUSTRATED BY A TYPICAL AND FATAL CASE,

by DR. HUNTINGTON RICHARDS, of New York.

The patient, a man aged twenty-six, came under observation March 8, 1890. Eleven months before a large polypus had been removed from the left auditory canal. The symptoms noted March 8th were earache and headache, with some mastoid tenderness. There was apparently a cicatricial drum membrane greatly depressed. There was an opening in it about three millimetres in diameter. A small polypus projected through the opening. A dose of calomel was ordered, and Bacon's artificial leech, followed by frequent douching, was advised. It was at this time deemed probable that an operation on the mastoid would be required. Four days later the drum membrane had become prominent. A Politzer inflation greatly increased the prominence. There was no redness or stenosis of the wall of the auditory canal. The drum membrane was adherent to structure posterior by a line along its middle, dividing the prominence into two portions. Three days later a portion of one of these prominences was removed by the snare. Three days later (18th) the auditory canal was much stenosed. There was swelling and tenderness in front of the ear, and some tenderness over the mastoid tip. The artificial leech was again applied with benefit. May 1st a polypus that had formed was removed. May 3d there was again mastoid tenderness. Discharge became profuse. May 5th the mastoid was operated on, but no trace of pus or of any true antrum was found. May 10th the temperature rose to 104.2° F., and the patient complained of violent headache. May 12th the attempt was made to extend the opening forward towards the tympanum by the use of Volkmann's spoon, without result. The opening was then enlarged by chisel and rongeur forceps until it became funnel-shaped, measuring twenty-seven millimetres in depth and twenty-seven by twenty millimetres in width. No antrum was discovered and no recognizable drum-cavity was opened and no accumulation of pus tapped. The day following the operation muttering delirium set in with diplopia, some slight convulsive movements of the orbital and facial muscles, complete ptosis of the left eyelid, and persistent tonic contraction of the muscles of the right side of the neck. The patient continued to fail, and died at 4.30 p. m. unquestionably of diffuse meningitis, and not improbably there was an inter-cranial abscess. No post-mortem could be obtained. It is possible, though far from certain, that an early and thorough operation for removal of the osseous and pus-confusing membrane would have accomplished what the two mastoid operations failed to do, namely, adequate outlet for pus, etc., and consequent saving of life.

In his paper the author urged the adoption of the expression "vault of the tympanum" or "fornix tympani" to designate that portion of the drum-cavity above the upper border of the tympanic ring. This

term is quite as appropriate as is the half facetious though conveniently brief "attic" of several recent writers. As to a supposed and most erroneously supposed Latin equivalent of the latter, namely, "atticus," it is hardly necessary to say that it is wholly inadmissible on linguistic grounds, there being no noun "atticus" in the Latin language, save the adjectival substantive used to designate an Athenian citizen. "Atticus" is not, never was and cannot now be, made the Latin term for a garret, attic or upper story of a house.

DR. S. THEOBALD, of Baltimore, reported

A CASE IN WHICH A SEPTUM CLOSELY RESEMBLING THE TYMPANUM MEMBRANE FORMED IN THE MIDDLE THIRD OF THE EXTERNAL AUDITORY CANAL, AND WAS REMOVED WITH IMPROVEMENT TO HEARING.

The septum, which was present only in the right ear, was about six millimetres nearer the outer extremity of the auditory canal than was the tympanal membrane of the opposite ear. It evidently had no connection with the ossicle, but moved out when the middle ear was inflated by the Valsalva method, and moved in again during the act of swallowing. There was a history of double otorrhea in childhood. After excision of the septum, it was found that the tympanal membrane proper was entirely destroyed, but the stapes and malleus were recognized *in situ*. The mucous membrane of the tympanal cavity was sclerosed and atrophied. A marked improvement of hearing followed immediately upon the removal of the septum. Further improvement was subsequently gained by inserting an artificial (cotton) drumhead. The hearing, which before the operation was equal to distinguishing words in a loud voice at twenty feet, was improved to words in a low voice and whisper at twenty feet. The septum showed a decided tendency to reformation, which had to be controlled by the application of chromic acid and a second resort to the knife.

The PRESIDENT: These membranes forming in the external canal have for their end a reparative action. I saw such a membrane form in a case of my own, where there had been otorrhea, with loss of most of the membrane for fifteen years. The discharge ceased under treatment, and there was the formation of a new membrane similar to that described by Dr. Theobald, only in my case it was much thicker. I consider that in most cases the formation of this membrane is a most satisfactory reparative result. I should be glad to see Dr. Theobald's case followed for some time, to see whether or not there was any return of disagreeable otorrhea.

DR. J. A. ANDREWS, of New York: A few years ago I reported to the Society a case similar to that of Dr. Theobald. The membrane closed about three-fourths of the canal. It was removed, and there was no return of the discharge.

DR. HUNTINGTON RICHARDS, of New York: I recently saw a case in which there were two closures, one at nearly the normal distance of the tympanic membrane, and the other close to the meatus. I removed the outside membrane, but hesitated to cut through the other, as in one or two cases where I have done so the evidences of improvement have not been great. I am now treating a similar case, where the stenosis is close to the position of the normal tympanic ring. I have cut away the lower portion of the ring with acetic acid to permit free exit of discharge.

DR. THEOBALD, of Baltimore: There was no return of the discharge in the few weeks that the patient remained under observation. The patient would undoubtedly have been willing to be more or less troubled with otorrhea to gain the marked improvement in hearing.

ON THE RENEWED EMPLOYMENT OF THE NASAL DOUCHE AND KINDRED PROCEDURES,

by DR. A. H. BUCK, of New York.

Several years ago attention was called to the danger of exciting ear trouble by the use of the nasal douche and similar procedures. For some time it seemed that this warning had been heeded. During the past winter and spring the author had seen a large number of these cases, and thought it advisable to again call attention to the dangers that may follow the use of the nasal douche. In a few instances the results of the inflammation have been severe, but in the majority they have been simply an increase of the subacute nasal and aural catarrh.

As a safer and equally efficient method of treatment the use of a spray was suggested. The following preparations were mentioned:

R	Eucalyptol.	:	:	:	:	35 gr. j.
Oil. Gantotheria	:	:	:	:	gr. 10.	
Menthol	:	:	:	:	3	gr. M.

If the patient objects to this, it may be substituted by

R	Listerine	:	:	:	:	1 part.
Water	:	:	:	:	:	3 parts.

In the presence of an accumulation of viscid mucus or of crusts, a stream of flowing water will doubtless prove more effective than a stimulating spray. If the latter is used freely and each time during the inhalation of a deep breath, crusts and mucus will speedily cease to play a part in the therapeutic problem. In no instance had he known the use of the mixtures mentioned to cause any unpleasant aural symptoms. The use of sprays must, however, be looked upon only as a valuable method of supplementary treatment, and not as a therapeutic procedure of the first order.

THE REMOVAL OF A BULLET FROM THE EAR, WITH THE ASSISTANCE OF THE GALVANO-CAUTERY,

by DR. LUCIEN HOWE, Buffalo.

The difficulty occasionally met with in removing a round, hard body from the auditory canal is well known. The first efforts in these cases should be made with a syringe. The writer wished in this paper to call attention to a method which may occasionally prove useful, and which, so far as he was aware, had not been before suggested.

April 30th, a boy seven years old was brought to him with a small bullet lodged in the lower part of the auditory canal. An attempt to remove it by syringing was first made, without avail. An attempt with forceps showed the foreign body firmly imbedded, and on account of its smooth surface, it was impossible to grasp it. It then occurred to the operator that it might be possible to melt into the lead the wire of a galvano-cautery, by means of which, when cool, it could be removed, or, if not, to at least roughen the surface to such an extent as to allow forceps to grasp the bullet firmly. The child was put under the influence of chloroform, and the wire was melted into the lead, and the ball was drawn to the narrow part of the

canal, where it became detached. The surface of the bullet was then roughened above and below, and with toothed forceps removed.

The speaker took the opportunity offered by the report of this case to express his firm conviction that we should use every effort to discourage the practice common among physicians of attacking every such foreign substance with a pair of forceps. By our own example and discussion, we should teach our brother practitioners how much simpler and safer an instrument we have in the syringe.

DR. A. H. BUCK, New York, made a supplementary report on the

ANATOMY OF THE ELEPHANT'S EAR.

DR. C. H. BURNETT, of Philadelphia, read a paper on

PERMANENTLY GOOD RESULTS OF EXCISION OF THE MALLEUS AND MEMBRANA TYMPANI, IN A CASE OF CHRONIC TINNITUS AND AURAL VERTIGO, AND IN A CASE OF CHRONIC SUPPURATION OF THE ATTIC DUE TO NECROSIS OF THE HEAD OF THE MALLEUS.

In the first case, all known remedies for the relief of catarrhal deafness, tinnitus aurium and vertigo failed to give any relief. The malleus being found adherent to the promontory, this was believed to be the cause of the retraction of the chain of auditory ossicles, impaction of the stapes, pressure on the labyrinth fluid, and the noises in the head, and intense aural vertigo. The patient was therefore etherized (May 22, 1888), and the membrana tympani and the malleus excised. The relief to the tinnitus and vertigo was instantaneous and complete, and the cure has been a permanent one for two years, thus proving the mechanical origin of so-called Menière's disease in many instances.

In the second case, a chronic purulent discharge from the attic cavity of the middle ear, due to necrosis of the head of the malleus of several years' duration, was promptly and entirely relieved by excision of the membrana tympani and the diseased malleus. The operation was performed in July, 1889. The purulent discharge ceased at once. A new membrana formed in the course of two months, and the hearing rose from nothing to twelve feet, for isolated words. There has been no renewal of the discharge up to the present time, one year from the date of operation, and the general health of the patient has greatly improved.

DR. B. ALEXANDER RANDALL, Philadelphia, contributed further notes on

THE SHARPNELL PERFORATION.

He remarked that in citing in his paper of the previous year, a series of 13 new cases among 500 patients in six months' practice and a total of 120 among 10,000 in a group of clinical workers, he had thought the frequency of the lesion sufficiently proven; yet, as the point had been questioned when his paper appeared, he had been noting such cases again since January 1st, As the result, he had 23 cases to report, observed among 500 new patients of the six months, three of which occurred in patients previously seen, but without recognition of such a perforation. His incomplete notes for the latter half of 1889 showed only four records of the lesion, but he was confident that many more had been seen and treated. Yet, even accepting this record as complete, it furnished a series of 27

cases among about 1,000; or 42 among the 1,500 patients seen during fifteen months = 2.8%.

Excision of the drum membrane and malleus had been done in two of the cases before reported, without any such brilliant result as to lead him to prefer this radical measure to the intra-tympanic syringing usually employed. He expected to adhere to the latter using as before the Annel syringe and the hollow lachrymal probe as the most satisfactory apparatus, and the peroxide of hydrogen and weak solutions of the mineral acids as the fluids.

The cases were reported in detail, with drawings of many of them, and the farther history of the former cases was appended.

DR. J. A. LIPPINCOTT, of Pittsburgh, reported a case of

MASTOIDITES INTERNA PURULENTA FOLLOWING ERYSPelas.

The ear became involved one week after the occurrence of a severe attack of erysipelas. There was no preliminary involvement of the throat or nose. The patient recovered after opening of the mastoid and syringing.

DR. NEIL J. HEPBURN, of New York, reported a case of

FRACURE OF THE MALLEUS HANDLE FROM THE INTRODUCTION OF A HAIR-PIN.

SOME CASES OF MASTOID CELL DISEASE WITH A FISTULOUS OPENING WHICH RECOVERED WITHOUT THE USE OF THE DRILL OR CHISEL,

by DR. OREN D. POMEROY, New York.

Four cases were reported in which recovery occurred by the use of Wilde's incision and careful antisepsis:

The first case was that of a woman, forty-nine years of age, who had a fistulous opening into the mastoid three-fourths of an inch deep. After waiting a reasonable time for the fistula to close from the bottom, the external wound was allowed to close. There was no untoward results.

The second case was that of a man, thirty-nine years of age, who had a fistula into the mastoid eleven-sixteenths of an inch deep, which healed before the external wound was closed.

The third case was that of a child, four months of age, who had an opening into the mastoid, extending forwards and inwards for one and a half inches. This had nearly closed, when the external wound was allowed to close.

The fourth case was that of a man, twenty-two years of age, who had an opening into the apex of the mastoid, which closed concurrently with the Wilde's incision.

None of these cases had enough systemic disturbance to suggest that anything was going wrong.

ANEURISM FIRST RECOGNIZED IN THE FUNDUS OF THE EAR, LATER APPEARING IN THE NECK,

by DR. CHARLES A. TODD, St. Louis.

May, 1880. Mr. C., forty-five years of age, came under observation complaining of pain in the left ear and symptoms suggesting furuncles. In 1858, he had severe otitis media in both ears for one week, followed by discharge which ceased without treatment. Some deafness has since existed. For the past seven or eight years he had noticed a pulsating sound, at first in

both ears, now in the left. On examination of the left ear, there was seen a circumscribed swelling on the floor of the meatus just in front of the membrana and entirely concealing it. It was soft and fluctuating. Filling the ear with water a distinct intra-aural pulsation could be seen. The swelling was lanced under the supposition that it was a furuncle. There was a free gush of blood and some three ounces of blood were lost before the flow could be stopped by tamponing. No pus whatever was seen. The tampon could not be permanently removed for several days. Compression by tampon was advised to be continued at home. August, 1880, it was learned that compression had afforded little benefit. Ligation of common carotid was suggested if symptoms were considered sufficiently severe.

March, 1883, patient was again seen. Electrolysis had been tried with asserted diminution in size. March, 1890, the aural tumor was still present, but in addition there was a large aneurismal swelling of the neck below the ear. The patient was then referred to a general surgeon and has not since been heard from.

DR. BLAKE'S PAPER DISK: CASE HISTORIES,
by DR. ROBERT BARCLAY, St. Louis.

The object of the paper was particularly to call attention to the application of paper dressings to the membrana tympani, first suggested by Dr. Clarence J. Blake of Boston, for the treatment of perforations of that structure. To demonstrate not only the advantages claimed for this method, but others modestly disclaimed, and its wide usefulness in other conditions than those defined for its applications when originally suggested, the following cases were reported:

CASE I. A lady twenty-eight years of age, with right-sided acute otitis media of twenty-four hours' duration. The right membrana tympani vibrata was found bulging. A deep incision afforded some relief. At the end of five days a perforation of the posterior superior quadrant of the membrana tympani. This was closed by the application of a paper disk. Seven weeks later the disk with attached epithelial plate was removed from the superior posterior canal wall. The perforation had healed and hearing was normal.

CASE II. A lady twenty-one years of age, sought relief from tinnitus and deafness of right ear. The left ear had been condemned as irreparably disabled by former inflammation. She had had otorrhea in childhood. Three years before, there had been a return of this trouble in the left ear. This was checked after one week's duration. This ear, however, remained deaf. With the right ear she could hear a moderate voice, with the left, a loud voice at two feet. Right middle-ear was the seat of chronic catarrhal inflammation. The membrana tympani of the left ear was perforated in the posterior inferior quadrant. Treatment somewhat relieved the symptoms in the right ear. Stimulating applications to the perforation induced its closure to one-sixteenth in diameter, when a paper disk was applied. Two days afterward the disk was still in place. Hearing in left ear was one-forty-eighth; while moderately loud voice could be heard at twenty-five feet distance. The disk was subsequently removed and the perforation closed. The hearing of left ear has steadily improved.

CASE III. A man thirty-five years of age, was seen with deafness, tinnitus, cough and otorrhea in left ear of two months' duration. Two circular perforations of

membrana tympani were found. The otorrhea was checked and a paper disk applied to each perforation with immediate improvement of hearing for the voice. It is thought that the relief may have been permanent as the patient did not return.

CASE IV. A woman thirty-seven years of age. Six weeks before coming under observation sustained a compound fracture of the skull involving both sides of the base, the bony tympana, membrana tympanum and right external auditory canal. There had been aural hemorrhage followed by otorrhea. There was a transverse rent of right membrana. Within thirty-five days the only open wound was a small perforation. A paper disk was applied, a little flexible collodion was painted over it. Within two weeks hearing became normal.

CASE V. A lady twenty-one years of age, with the left membrane almost entirely sloughed away. A paper disk was applied. Within twenty days the watch could be easily heard off the left auricle. The hearing has steadily improved.

CASE VI. A man twenty-two years of age, had prolonged otorrhea on right side in childhood. For past three weeks had deafness in both ears. Left ear was the seat of chronic catarrhal otitis media. Right ear shows two perforations. These closed in seven weeks. There was marked improvement of the hearing.

CASE VII. A youth nineteen years of age, had been subject to bilateral otorrhea since the age of six months. Perforation of right membrana tympani was found. After cessation of otorrhea, paper disks were applied. The perforation promptly closed with improvement of hearing.

CASE VIII. A man nineteen years of age, had otorrhea in childhood. During past eight years has had recurring attacks of otorrhea on left side. The left membrana tympani was greatly thickened and perforated. The discharge ceased in nine days and under stimulating treatment the size of the opening diminished. In the fourth week the first paper disk was applied. Four days later the hearing for the watch was $\frac{3}{4}$. The perforation has subsequently closed.

CASE IX. A physician, forty-eight years of age, had sustained a rupture of both tympanic membranes in diving thirty-four years before and for over thirty years had intermittent otorrhea. A perforation in the right membrana tympani was found. This promptly healed under the application of a paper disk. The hearing greatly improved.

Conclusions: From the case histories given may it not be considered demonstrated that Dr. Blake's paper dressings have these therapeutic advantages already claimed; applied to a perforation of the membrana tympani, it performs in a great measure, the functions of the lost membrane, (1) improving the hearing from the time of application, (2) maintaining a normal degree of moisture and temperature in the air of the tympanic cavity, (3) protecting the enclosed tissues from direct influence to atmospheric influences, and (4) excluding organic and inorganic foreign bodies approaching from the external auditory canal, (5) it acts as a local irritant to the edge of the perforation only, thereby inducing reproduction of the lost membrane, (6) as a splint protecting it when forming and preventing its displacement in either direction.

May we not accredit this method with these additional advantages hitherto unclaimed: (1) Improve-

ment in hearing may subsequently result from cicatricial closure of the perforation, not at once appreciable on application of the paper disk; (2) the paper dressing may prove serviceable even where the perforation is quite large; (3) it may be used to advantage where indeed the outer surface of the membrana tympani has not returned to its normal condition; (4) it may prove a serviceable artificial membrana tympani where that structure is almost entirely lost; (5) at the same time may stimulate reproduction thereof; (6) it may serve as a splint when applied to manometric tissue; (7) it may induce conservative structural modification thereof and (8) may by acting here as an artificial membrana tympani at the same time improve the hearing.

A failure to secure satisfactory results is not to be attributed to the method, experience proving that discriminating judgment and skill in its application are largely essential to its usefulness.

The following officers were elected: President, Dr. Gorham Bacon, New York; Vice-President, Dr. Huntington Richards, New York; Secretary and Treasurer, Dr. J. J. B. Vermyne, New Bedford, Mass.; Committee on Membership, Drs. Arthur Mathewson, Brooklyn; Samuel Theobald, Baltimore, and S. D. Risley, Philadelphia; Committee on Publication, Drs. J. J. B. Vermyne, New Bedford; C. J. Blake, Boston, and J. Orne Green, Boston.

The following were elected to membership: Dr. Frederick L. Jack, of Boston; Dr. J. B. Shapleigh, of St. Louis; Dr. Benjamin J. Baldwin, of Montgomery, Ala.; Dr. J. M. Ray, Louisville, Ky., and Dr. F. U. Ring, of New York.

The Society then adjourned.

Recent Literature.

The Gulstonian Lectures on Secondary Degenerations of the Spinal Cord. Delivered at the Royal College of Physicians, March, 1889, by HOWARD H. TOOTH, M.D., F.R.C.P., etc. Octavo, pp. 71, with 14 illustrations. London: J. & A. Churchill. 1889.

To the student of the fine anatomy of the spinal cord, this careful study is a necessity. Dr. Tooth's personal researches are based upon various cases of transverse lesion of the cord in man, and upon experiments made upon monkeys by Mr. Victor Horsley. In addition, however, the author has incorporated into these lectures many of the results reported by other investigators. The first lecture is devoted to the study of the pathological changes of degeneration. The so-called traumatic degeneration is essentially inflammatory, and embraces the whole region about the lesion, irrespective of special tracts. Secondary degeneration is visible in six days. Secondary degeneration in the cord is due to destruction of trophic centres, interruption in the continuity of fibres, or section of the posterior roots; it is not the same as Wallerian degeneration of the nerves; the fibre is rendered useless, and its place is gradually taken by thickened neuroglia. The process is usually complete in six months. In the peripheral nerves the fibre dies, but regeneration also occurs. Tooth doubts whether anything like a regeneration of cord fibres ever occurs. The next two lectures are devoted to the study of ascending and descending fibres in the various tracts of the cord, — a

subject of the utmost importance to our knowledge of anatomy and physiology. The student will find in this admirable presentation an admirable guide to the subject. Space is lacking to point out the various data collected, but we must call attention to the section on the visceral fibres of the cord, medullated fibres of the finest calibre, efferent and afferent, which have long been observed, although their significance has been unknown. The author calls attention once again to these fibres, and suggests the importance of a careful study of them in all obscure cases of nervous disturbances of the viscera. Although appealing primarily to the specialist, this monograph is one the perusal of which would repay every physician. P. C. K.

Recherches Cliniques et Therapeutiques sur l'Epilepsie, l'Hystérie et l'Idiotie. Par BOURNEVILLE, SOLLIER, PILLIET, RAOULT, BRICON et COURBARIN. Octavo, T. viii, pp. ix, 263, with 27 illustrations. T. ix, pp. ix, 92, with 25 illustrations. Publications du Progrès Médical, Paris. 1888, 1889.

These two volumes sum up the work of the service for epileptics, idiots and feeble-minded, at Bicêtre, for the years 1887 and 1888. The first part of each volume is devoted to tables of statistics, an account of the new contagious ward, isolated ward and dormitory, and an illustration of some of the methods employed in the management and instruction of idiots. The second part is clinical, and contains various articles, based on observations at Bicêtre, many of which have already appeared elsewhere. The most important of these is a long article, in the eighth volume, by Bourneville and Bricon, on procursive epilepsy, a form of epilepsy attended with rapid propulsion in a straight line or in a circle, seldom attended with a fall or followed by coma, but complicated with marked congestion of the face. The relations of these attacks to the procursive aura, to post-epileptic procursion and to automatism are pointed out. Procuration itself is thought to be due, as far as the few autopsies give any light, to some cerebellar lesion. The prognosis, as in all forms of epilepsy, is grave. The other most important papers in this volume are one on two cases of double atrophy with imbecility by Bourneville and Pillier, and one on dentition in idiots by Sollier. In the ninth volume, Bourneville reports another interesting case of myxedematous idiocy, and Bourneville and Courbarin study the rôle of consanguinity of parents in the aetiology of epilepsy, idiocy, imbecility and hysteria. Their conclusions are, that healthy consanguinity has no effect, but that where the parents are defective, consanguinity intensifies the probability of defect in the offspring. P. C. K.

A Treatise on the Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D., LL.D. Fifth American, from the Seventh English Edition, with Notes and Additions, by ROBERT P. HARRIS, M.D. Philadelphia: Lea Brothers & Co. 1889.

This work is too well-known to require extended notice as successive editions appear. The most important changes noted are in the sections on the Porro operation, on the conservative Cesarean operation, and on the treatment of extra-uterine pregnancy. We see with pleasure that the new obstetric nomenclature has been adopted in this edition; but we regret that the distinguished author has thought best to retain the autogenetic theory of puerperal sepsis.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JULY 31, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 28 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
 283 WASHINGTON STREET, BOSTON, MASS.

THE CONTROL OF SYPHILIS.

THE subject of State control of syphilis is a very vital one, which forces itself upon the notice of the profession with great emphasis. There can be no question that the evil has become one that deserves some attention at the hands of those who provide for the preservation of public health. The disease holds a singular position, in that, in common with other venereal diseases, it is shut out from the charity of our public hospitals. The exact reason for depriving venereal patients of hospital treatment may not necessarily have been anything more than that they were not considered the class upon whom public charity should be expended. But the conditions have changed. They have become a menace to the public health, and for self-protection some action should be taken.

Syphilis is, however, only nominally a venereal disease. It is the large proportion of cases of non-venereal syphilis, *sypilis insontium*, which gives the disease its importance.

In discussing the subject of State control in 1887, Fournier gave as the proportion of women in his private practice who had received the disease without wrongdoing on their part as nineteen per cent. This result was reached after throwing out all doubtful cases. Dr. Greenough, in the discussion which we publish to-day, puts the percentage of women innocently affected in his dispensary practice as more than fifty per cent. It must be remembered that these innocent women are not all even the wives of unfaithful husbands,—some are the wives of men who have been themselves accidentally inoculated from a common pipe or drinking glass.

Public opinion has somewhat changed in regard to the charity to be bestowed upon evil-doers. It is a more commonly accepted idea that the regeneration of the sinner is most easily introduced by the care of his physical ills. The missionary is now also a physician, or is accompanied in his field of labor by a physician, and missionaries have been found in the class-room with medical students, studying syphilis as one prelim-

inary or assistance to their missionary work; and surely, in our own country, the day has gone by when syphilitics must be considered as beyond the reach of compassion and assistance.

The strict regulation and control of syphilis, as is attempted in some foreign countries, is out of the question in the United States, nor is there very good reason to desire such a method. Its success is not unquestioned, even in the countries where the regulations are most strict. Some other method must be found here, and the first and most obvious is the establishment of hospital accommodations. There is room for two opinions as to the propriety of letting down the bars which rule in out of general hospitals. It may not be best to do so; but some provision can be made, and is demanded for public safety. Even private charity might find a most worthy object in establishing suitable hospital provision for syphilitics.

There is one method of bringing public attention to the evil, which ought to be put in practice. Syphilis might well be included in the same quarantine regulations that exclude patients with leprosy from entering the country. The number thus excluded would probably be but a tithe of the number that now annually enter our ports to become a burden to the community; but the effect of the exclusion of a single individual would have a wide result for good, in deterring others from emigrating.

THE INSANITY OF CARDIAC DISEASE.

ACCORDING to Bull (*Médecine Moderne*, No. 29, p. 577) mental alienation, due to disease of the heart, is relatively rare.

Nasse, in 1818, first wrote of cardiac insanity as a special psychosis. Since then, numerous treatises have appeared on the subject; notably those of St. Germain-Limbo, Astros, Duriez, Sancerotte, Norel, Armanguet, etc.

It has long been remarked that sufferers from heart disease occasionally present peculiar mental symptoms. They are emotional, irritable, peevish, get angry at the least trifle, while, at the same time, possessing great mental and bodily activity. These psychical peculiarities do not amount to mental alienation, but they constitute a tendency of mind on which insanity may graft itself.

What are the two fundamental conditions necessary to constitute cardiac insanity?

First and foremost, a lesion of the heart, then a particular disposition of the cerebrum. The cardiopathy is the *sine qua non*; what it is important to remember is that the insanity generally breaks out during an exacerbation of the cardiac symptoms. One of Bull's patients felt his suicidal impulses only when the palpitations, the painful constriction of the thorax, the dyspnoea came on. "These accidents (the insane manifestations) made their appearance chiefly when the patient was standing, and when he was leaning his head forwards, thus producing anæmia of the bulb

and congestion of the frontal lobes; they rapidly disappeared when he lay down on his back. The morbid impulse vanished with the respiratory distress."

As for the particular heart-lesion, it is generally agreed that mitral affections are the most influential in bringing on this psychosis; next in order come the ventricular hypertrophies, and lastly, aortic insufficiency, a lesion which is peculiarly prone to anaemiate the bulb, and give rise to the anguish and dyspnoea so characteristic of Corrigan's disease.

We are hardly yet in possession of the knowledge which might enable us to refer special kinds of insanity to particular kinds of lesions. Patients may be affected with all forms of cardiopathy without mental alienation, while the great majority of the mentally unsound have no lesion of the heart whatever. But melancholia, doubtless, oftener coincides with heart disease than with any other psychosis. There exists a cardiac hypomania accompanied with a restlessness and an agitation which bears a marked resemblance to "anxious melancholia," that is, a delirium with predominance of sad ideas, and with an exaggerated tendency to noisy lamentations, and an irresistible tendency to continued movement.

Burman considers hypochondriac melancholia as the type of cardiac insanity; to this he joins the delirium of suspicion, and a particular mental state in which the subjects are at once impulsive and depressed.

It has been remarked that all the victims of cardiac insanity are extremely prone to suicide, and that the morbid impulse is especially apt to manifest itself on the occasion of an aggravation of the circulatory troubles. The delirium is peculiarly a delirium of the night time, as Corvisart has remarked. It has, moreover, been noted that the supervention of albuminuria is one of the most important factors in the production of the delirium. A cardiac patient in the full possession of his reason will show signs of mental derangement, will have delirium, hallucinations, morbid impulses as soon as the least cloudiness of albumen appears in his urine. This circumstance suggests the possibility of the delirium being uremic in these cases.

The one feature which soonest attracts attention in the evolution of cardiac insanity is the intermittent march of this psychosis; it manifests itself paroxysmally, its accessions being habitually followed by remissions supervening under the influence of rest and treatment.

In making a diagnosis of cardiac insanity, it is necessary to lay great stress on the fact of a cardiopathy anterior to the disorders of intelligence; then the remittent character of the delirium, and its coincidence with manifest troubles in the functions of the heart will be important elements of diagnosis.

A third character, to which great importance is attached, is the precordial distress which precedes and accompanies the explosion of the delirium.

In the treatment of this kind of insanity, great reliance must be placed on the heart tonics, especially on

digitalis, frequently administered in small doses; it has been found that large doses rather aggravate than arrest the delirium. Bull speaks highly of the utility of hypodermic injections of sparteine and morphine, which have a very rapid action in arousing and sustaining a fatigued and flagging heart. The sedative action of the alkaline bromides on the nervous system constitutes them a precious auxiliary. Repose and isolation are indispensable; it will often be necessary to send the patient to a sanitarium, or even to an asylum; sometimes a sea voyage will give just the rest and freedom from care and business that is needed.

MEDICAL NOTES.

—The Boston *Transcript* having said that "we have a ridiculous surplus of doctors in the United States," the *Traveller* asks if the *Transcript* can mention any profession that has not a surplus of practitioners? We object to the expression "ridiculous." It might be ridiculous if it were not extremely pathetic.

—The New York State Care of Insane Act requires that all doctors who have been granted certificates of examiners in lunacy by a judge of a court of record as required by law, shall file a copy of such certificate in office of the State Commission in Lunacy.

Commitments of persons signed by physicians who have not filed such a certificate have been received in the office of the State Commission in Lunacy, and have been declared illegal. Commissioner Brown says the law will be strictly enforced in this respect.

—The *Path*, a journal of theosophy, in its current number contains the following calm description of the objects and methods of vivisection: "Through a creature crucified alive to a plank, cut into with knives, torn with burns, burnt with acids or hot irons, pierced through and through with nails, scalded inside or outside with boiling water, wetted with spirits and set on fire, whose eyes and organs and limbs are dissected out bit by bit, whose nerves and sinews are wrung to their utmost tension with hooks, whose whole circulation is deranged and whose frame is writhing throughout with agony — Nature permits no trustworthy revelation to be made."

—The New York *Star* mentions three physicians of that city who have forsaken the path of medicine for the thornier one of financial speculation and, strange to say, all of them with marked success so far as the attainment of wealth. One is Dr. J. H. Parker, just elected vice-president of the Park National Bank, who made the first steps toward his fortune, estimated as in the millions, from cotton speculation, having formerly been a medical practitioner in Charleston, S. C. The second is Jesse Seligman, of Seligman Brothers, who was about to hang out his sign as a doctor in San Francisco during the gold excitement of 1848-49, but drifted into the banking business instead. The third is Dr. Norvin Green, president of the Western Union Telegraph Company, who came from Kentucky, and at one time made a specialty of lung diseases.

— Dr. Audie Sarzeau, in the *Pharm. Zeitung* (*Pharm. Journal*, p. 792, 1890) directs attention to the considerable solvent action of camphor upon iodoform. He found that it requires ten grammes of alcohol for the solution of .125 gramme of iodoform, yet the quantity of the latter dissolved is one gramme if the alcohol be first saturated with camphor.

— The New York *World*, which is nothing if not enterprising, has matched its recent performance of Nellie Bly with the doctors by a similar trial on the druggists. A reporter took two prescriptions around to thirty-six drug stores, had them compounded, paid for them, took receipts, then went home and wrote a three-column article, which was duly published in the *World*. The two prescriptions, as priced by "a prominent member of the drug jobbing trade," were as below :

PRESCRIPTION NO. I.

Sulfonal	is valued at \$1.35 an ounce.
Sulfonal, grs. xv, cost	4 cents 73 mills
Bismuth, sub. carb., ½ dram, cost	1 cent 5 mills
Cretac prep., grs. x, cost	0 cent 2½ mills
Total.	5 cents 15 mills
Equal to 6½ cents.	

PRESCRIPTION NO. II.

Tinct. opii camph. 1 ounce, cost	2 cents 5 mills
Mist. glycyrrh comp., ½ ounce, cost	1 cent 73 mills
Syr. acacia, ½ ounce, cost	1 cent 2½ mills
Total.	4 cents 15 mills
Equal to 6½ cents.	

Thus twelve cents was the actual cost of the materials in the prescriptions, and the reporter becomes excited when, upon comparing receipts from the stores where he had the medicines compounded, he finds he has paid sums ranging from thirty-five cents to eighty cents, and immediately resorts to mathematics to show that the druggists have made from 300 to 400 per cent. profit. It is quite fair for the druggists to protest that the reporter has figured at *nil* the manipulative skill of the druggist, and what is worth more, the responsibility for the handling with accuracy of powerful remedies.

— Mr. C. S. Loch, an active officer of the London Charity Organization Society has printed in *Murray's Magazine* a very complete and interesting analysis of Medical Relief in London. In London there are eleven hospitals with medical schools at which over 44,000 in-patients and over 550,000 out-patients are treated annually, and the medical students find in them the best means of perfecting their preparation. London has eight general hospitals without schools, caring for 5,600 in- and over 107,000 out-patients. It has 56 special hospitals with over 26,000 in- and 398,000 out-patients. London has 39 dispensaries with over 260,000 patients, and of late, instead of giving medical advice and treatment and medicine free, successful efforts have been made to discriminate in favor of those really entitled to such wholesale charity. Then London has 44 dispensaries maintained by the tax-payers, caring for over 114,000 patients. The hospitals built and supported by taxes supply over 11,900 beds. Out of a total of 23,539 beds in its hospitals, 17,830 were occupied, the differ-

ence being due to want of funds, not of patients. The nominal deficit of the London hospitals is about half a million dollars a year — that sum is needed to enable them to use all their accommodations.

— Many strange ideas of hospitals and hospital appointments are being aired just now before the Lords Committee, as we learn from the *London Lancet*, and many vague and contradictory statements are made as to matters of fact which are apt to prejudice the public, or to convey an impression that witnesses are speaking at random and without that precision which is always to be expected in professional men. One view of the honorary surgery to a great hospital came out rather strongly in the evidence of one witness — namely, that it involved great sacrifice on the part of the surgeon. The gentleman was of the opinion that the honorary surgery to a well-known hospital cost him very dear — lost him, in fact, £2,000 a year. This is one way of putting it; but, as our contemporary points out, a very one-sided way. "A surgeon devotes time to hospital work, but the work and the appointment give him reputation. He is not asked to hold the appointment longer than suits his own convenience. He can fix his private work for any hours and days which suit his hospital engagements. A dozen young rivals will only be too happy to relieve him of his hospital appointment, and to them it would not mean a loss of £2,000 a year. We do not undervalue the great services to hospitals rendered by surgeons of secured fame. But they must not ask the public to pity them too much. It is not a form of martyrdom that can be too much magnified."

♦ ♦ ♦
Miscellan.

M. PASTEUR AND HYDROPHOBIA.

An article by Thomas M. Dolan, M.D., in the *Contemporary Review* for July, contains a strong arraignment of the success of the Pasteurian treatment against hydrophobia. We make room for a few extracts:

"It is now thirteen years since . . . I investigated carefully a number of cases of alleged cures by a clergyman residing near Burnley, who had a great reputation in Lancashire for the cure of hydrophobia. The result of my inquiry showed that the Rev. Dr. Verity, the clergyman in question, had had a large number (two thousand) of dog-bitten patients. A few of them had died from hydrophobia after his treatment; but the majority escaped, the reason being that they had been bitten by non-rabid dogs, or had been bitten through clothing, etc. I inquired into numerous other alleged cases of cure of hydrophobia, but always with the same result; and I was thus led to formulate this proposition, — 'that if any one obtained a reputation for the prevention of hydrophobia, and if all the dog-bitten sought or took this remedy, the result would be statistically favorable.'

"I found, on carefully comparing the statistics given by M. Pasteur with those of the years which preceded the introduction of his system, that the supposed rabid dog-bitten in France had increased in extraordinary proportions; while, at the same time, the average

mortality from rabies in France had shown but little fluctuation.

"In explanation of the deaths, a general affirmation was made that the cases that died came 'too late.' But, in looking through the list of patients, I found that the cases which were 'cured' were, in many cases, of just as long duration, and that with regard to them no assertion was made that they came 'too late.' Take, for instance, the case of Lord Doneraile. If, in his case, eleven days was too late for treatment, then all cases that came after that period had elapsed must be expunged from the list of cures. Or, if Lord Doneraile's death was due to the application of the weak or first method, then the cases of the others treated by the same formula fall to the ground.

Dr. Dolan cites the classification which Pasteur has adopted with regard to the proofs that the patients he has treated were bitten by dogs that were really suffering from rabies. The following is the form adopted: Class A. Cases in which the dog was proved to be rabid by the experimental test; Class B. Cases in which the dog was recognized as rabid by the veterinary surgeon; Class C. Cases in which the dog was only suspected of being rabid.

"This classification presupposes that all the patients have been exposed to danger. It makes no allowance for non-rabid dogs, with the strange result, that, according to these statistics, a veritable epidemic of rabies, affecting thousands of dogs, must have existed in France during the years which have elapsed since M. Pasteur introduced his system.

"Dr. Dujardin-Beaumetz, Director of the Sanitary Service of Paris, has addressed to the prefect of police a report on hydrophobia in Paris, furnishing the following data of comparison:

"For the four years antecedent to Pasteur the deaths were 38, namely, in 1882, 9; in 1883, 4; in 1884, 3; in 1885, 22.

"For the four years of treatment the deaths were 37, namely, in 1886, 3; in 1887, 9; in 1888, 19; in 1889, 6.

"On November 2, 1887, M. Pasteur wrote to the Academy of Medicine as follows: 'We know that sixty persons have died in the Paris hospitals during the last five years, a mean of twelve per year.'" After careful investigation of the hospital returns for those years, Dr. Dolan contradicts this statement, and submits a full list of the names of all the patients who died in the Paris hospitals during that time, showing the following results: in 1881, 11 died; in 1882, 3; in 1883, 4; in 1884, 3; in 1885, 5. This gives a total of 26, or an average of 5.2 per annum, in place of the annual average of 12, as estimated by M. Pasteur, of French patients treated by him, who have "died since the introduction of the Pasteurian system." The following is a recapitulation: in 1886, 19 deaths; in 1887, 27 deaths; in 1888, 23 deaths; in 1889, 21 deaths; giving a total of 80, or a yearly average of 20. These cases only represent the deaths after inoculation by M. Pasteur. To obtain the annual mortality of rabies in France, we must add to the foregoing the deaths of those persons who have not been treated at the institute. According to statistics published by M. Pasteur himself in 1886, the deaths among the non-inoculated for that year amounted to 17. If these be added to the 19 who died after treatment, we have an annual mortality of 36, as against an annual mortality, according to Tardieu's returns,

prior to the introduction of inoculation, of 25 to 30. With these statistics before us, we are forced to the conclusion that the words of Sir James Paget in his recent address at the Mansion House were prompted more by generous impulse, and by feelings of respect and friendship for Pasteur, than by any strict regard to statistical data. As we have seen, Sir James Paget fixes the general mortality of those bitten at 15 per cent. M. Pasteur, in his article in the *New Review* (December, 1889), accepts this estimate, but thinks it is too low for bites on the face and other exposed parts. In such cases he thinks that the figures should be from 60 to 90 per cent. If we add up the number who have been bitten on exposed parts, and accept these percentages, then M. Pasteur's saving of life has been much greater, and his cures for France alone amount to some hundreds per annum. When we remember the ascertained mortality in France, and the rarity of hydrophobia there in past years, such percentages as the foregoing reduce the system to an absurdity."

TENOTOMY TO INCREASE THE MOBILITY AND POWER OF THE MUSICIAN'S RING-FINGER.

CONSIDERABLE attention having been lately attracted to the above subject we subjoin extracts from a paper by Dr. F. W. Langdon, in the Cincinnati *Lancet Clinic*, for July 5, 1890:

"The limited range of independent extension possessed by the fourth digit of the hand is well known, and is usually a most formidable stumbling-block to the pianist and other performers on keyed and stringed instruments, in the production of certain notes, and musical effects, as trills for example.

"The causes of this impairment of mobility, which is associated with a corresponding lack of power in the digit, are two in number, namely: (1) mechanical, due to structural peculiarities of the parts; and (2) physiological, due to insufficiency of muscular development; the latter being dependent on the former.

"The mechanical obstacles to free extension, as any one may satisfy himself by dissection, or even by examination of the average living hand, are two oblique tendinous bands, situated about three-quarters of an inch above the knuckle line, connected proximally with the extensor tendon of the ring-finger and distally with the common extensor tendons on either side, namely: those to the middle and little fingers.

"That these subsidiary tendons act as 'guy ropes,' and limit the extensor range of the ring-finger especially, may be determined by any one for himself, by placing the hand on a flat surface and extending, first, the ring-finger alone; then extension of its neighbors on either side will demonstrate that all three can be brought higher than either one alone. The little finger is seen to be less affected than either of the others, owing to its possession of a proper extensor, which is free, while the middle finger is less limited than the ring, by reason of having the 'guy' tendon on one side only.

"These diagonal tendinous bands are constantly present, though varying somewhat in development and position in different persons.

"Not only is extension of the ring-finger diminished, but separation of the three inner digits is materially lessened by the presence of these apparently insignifi-

cant slips, so that the lateral "spread of the digits is impaired to such a degree as to become an important matter to the musician. Again, in addition to the mere limited range of motion, both vertically and laterally, due to the mechanical effects of these slips, there is also to be considered the physiological factor, namely, lessened functional activity and consequently faulty development of the muscular fibres acting on the extensor tendon of the ring-finger, namely, fibres of the common extensor, fourth dorsal interosseous and third lumbricalis. This fault of development is a more important matter than would appear at first glance, since it is mainly by the interossei and lumbricals that the first phalanges are flexed and the second and third extended, whence the name 'fiddicinates.'

The performance of the operation in one case is thus described. "The field of operation was prepared by thorough cleansing. The skin, with a large branch of the dorsal venous arch, was now slipped aside with the thumb, so as to leave clear of vessels the interspace between the third and fourth metacarpals in the neighborhood of the proposed incision. Moderate flexion of the patient's hand enabled the operator's finger to define the position and direction of the outer (radial) connecting slip, which varies slightly in different subjects; its middle averaging perhaps three-quarters of an inch above the knuckle line. With an ordinary sharp-pointed tenotomy knife a longitudinal incision, one-eighth inch in length, midway between

the third and fourth metacarpals, and just to the distal side of the slip to be divided, is carried through the skin and superficial fascia. The exact location of the slip having now been determined by means of a probe — the deep fascia is incised at the lower edge of the slip and the point of the knife carried directly upward, that is, toward the wrist, beneath the slip, which parts with the characteristic creaking sound and feel. If not sufficiently tense to divide easily, it may be made more resistant by directing the patient to flex the fingers a little more strongly. The dressing consisted of a pledget of absorbent cotton held in place by adhesive strapping.

"A marked increase in range of independent extension was at once evident, and within a few days the patient remarked a greater precision of touch — there being no tendency to the lateral twisting which had before annoyed him — and which was at this time observable in the other hand. Union of the wound was complete when the dressing was removed on the third day, and the result of the operation was so satisfactory to the patient that he at once submitted the other hand to be operated on. The motion attained in both cases was so satisfactory that it was deemed unnecessary to divide the slip going to the little finger tendon. In some extreme cases, however, this also would probably require division, in which event it would be well to bear in mind its lesser length, and not mistake for it the common extensor tendon, going to the fifth digit."

REPORTED MORTALITY FOR THE WEEK ENDING JULY 19, 1890.

Deaths reported 3,185; under five years of age 1,673: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 963; consumption 384; acute lung diseases 175; diarrhoeal diseases 785; diphtheria and croup 78; typhoid fever 48; whooping-cough 43; measles 16; scarlet fever 12; malarial fever 12; cerebro-spinal meningitis 8; erysipelas 3.

From whooping-cough, New York 15, Brooklyn 11, Philadelphia 7, Baltimore 3, St. Louis, Boston, Washington, Charleston, Cambridge and Salem 1 each. From measles, New York 11, Brooklyn 2, Baltimore, Washington and Lawrence 1 each. From scarlet fever, New York 7, Philadelphia and Brooklyn 2 each, Baltimore 1. From malarial fever, Baltimore 6, Brooklyn 5, Nashville 1. From cerebro-spinal meningitis, Washington 3.

The meteorological record for the week ending July 19, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending Saturday, July 19, 1890.	Barom- eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.*		Rainfall. Duration, Hrs. & Min. Amount in Inches.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 26, 1890.

STONE, L. H., assistant surgeon, ordered to the U. S. Receiving-Ship "New Hampshire."

UXOR, J. F., assistant surgeon, detached from the U. S. Receiving-Ship "New Hampshire," and ordered to U. S. Receiving-Ship "Wabash."

NORTON, OLIVER D., passed assistant surgeon, granted leave of absence for month of August.

BABIN, H. J., surgeon, granted one month's leave of absence from July 23d.

OBITUARY. JACOB ROBERTS, M.D.

Dr. Jacob Roberts, who died at his residence, in Philadelphia, July 20th, of cerebral hemorrhage, was born in that city on March 21, 1838. He graduated at the University of Pennsylvania in 1862, and soon afterwards entered the regular army as a medical cadet, and was afterwards commissioned by Governor Andrew, of Massachusetts, as an assistant surgeon in the Twenty-third Massachusetts Infantry. He was with his regiment on three battlefields, but his duties for the most part were in the hospitals. After a service extending over two years he resigned, and began the practice of his profession in Philadelphia, in which he met with great success. For many years he was associated with Professor Goodell, of the University of Pennsylvania, in conducting a lying-in charity.

BOOKS AND PAMPHLETS RECEIVED.

Session of 1890-91. Annual Announcement of the New York Polyclinic and Hospital, a Clinical School for Graduates in Medicine and Surgery.

A Treatise on Rheumatism and Rheumatoid Arthritis. By Archibald E. Garrod, M.A., M.D., Oxon., M.R.C.P., etc. With charts and illustrations. Philadelphia: P. Blakiston, Son & Co. 1890.

Brooklyn 2, New York 1. From erysipelas, New York, Brooklyn and Boston 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending July 12th, the death-rate was 17.7. Deaths reported 3,308: infants under one year 636, diarrhoea 177, measles 163, whooping-cough 112, scarlet fever 70, diphtheria 36, fever 26.

The death-rates ranged from 10.4 in Norwich to 25.3 in Newcastle-on-Tyne: Birmingham 19.2, Bradford 13.9, Hull 11.7, Leeds 18.1, Leicester 19.9, Liverpool 22.8, London 17.4, Manchester 23.1, Nottingham 12.8, Sheffield 16.9, Sunderland 19.9.

In Edinburgh 16.7, Glasgow 23.0, Dublin 21.3.

Fact and Theory Papers. Protoplasm and Life. Two Biological Essays. By Charles F. Cox, M.A. New York: N. D. C. Hodges. 1890.

The Nature of the Giant-Cells of Tubercle and the Elements Associated Therewith, as Seen in Comparative Pathology. By Walter K. Sibley, M.B., B.C., B.A., Cantab. Reprint.

Railway Hygiene, and the Necessity of Sanitary Inspection and Supervision of Railway Coaches, Buildings and Grounds. An Address to the Association of Railway Surgeons at Kansas City, Mo. By G. P. Conn, M.D., Concord, N. H. 1890.

Familiar Forms of Nervous Disease. By M. Allen Starr, M.D., Ph.D., Professor of Diseases of the Mind and Nervous System, College of Physicians and Surgeons, New York. With illustrations, diagrams and charts. New York: Wm. Wood & Co. 1890.

Diseases of the Rectum and Anus, Their Pathology, Diagnosis and Treatment. By Chas. B. Kelsey, A.B., M.D., New York, Professor of Diseases of the Rectum, at the New York Post-Graduate Medical School, etc. Third edition, rewritten and enlarged, with two chromolithographs and 168 illustrations. New York: Wm. Wood & Co. 1890.

Extra Uterine Pregnancy. The History of, by Dr. G. W. Millerberger; Laparotomy for, with Report of a Successful Case, by Dr. T. A. Ashby; Review and Discussion, by Dr. H. A. Kelly; General Discussion. Papers read before the Obstetrical and Gynaecological Society, of Baltimore City, January 14 and February 11, 1890. Published by order of the Society.

Über Feuerbestäubung. Vortrag gehalten am Abende des 12. Februar, 1890, im Verbindung mit Experimenten und Vorlesungen von kolorettalen Bildern in Natur und künstlichen Verbrennungen zu Mühlhausen im Elsass. Neben Anhang und mit fünf Abbildungen im Texte, von Prof. Dr. Friedrich Goppele-Röder. Druck und Verlag von Wenz & Peters, Mühlhausen i. Els.

An Investigation into the Etiology of Phthisis. By Henneage Gibbs, M.D., Professor of Pathology in the University of Michigan; and E. L. Shurly, M.D., Professor of Laryngology and Clinical Medicine in the Detroit College of Medicine. Part II. On the Clinical History of Phthisis Pulmonalis. By E. L. Shurly, M.D. Part IV. On the Etiology and Local Treatment of Phthisis Pulmonalis. By E. L. Shurly, M.D. Reprints. 1890.

Original Articles.**SOME POINTS IN THE TREATMENT OF GONORRHEA.¹**

BY GARDNER W. ALLEN, M.D.,
Surgeon in the Genito-Urinary Department, Boston Dispensary.

THE ANTERIOR URETHRA.

The fact that gonorrhœa, even under favorable conditions, has a strong tendency to become chronic, and the acknowledged difficulties encountered in treating the disease in its later stages, give it an importance to the physician perhaps out of proportion to the seeming insignificance of the symptoms. A slight urethral moisture, without subjective symptoms, will sometimes keep the patient in a state of worry and depression, and the physician at his wits' end, trying one remedy after another, for months; yet, if Noegele's teachings are to be followed, and they are apparently gaining more and more advocates among the gynecologists, the importance of absolute extinction of the disease in every case can scarcely be exaggerated.

Various forms of treatment are, from time to time, recommended, promising quick and permanent cure for gleet; but most of them are disappointing. The reports of such brilliant results are probably based on too small a number of cases. Chronic urethritis is an uncertain as well as an obstinate affection. It occasionally happens that a slight chronic discharge will stop spontaneously, almost abruptly, and sometimes a sound passed two or three times, or a simple injection for a few days will check a discharge, and relieve symptoms that have been going on a long time; but such cases are the exception, not the rule, and should not be cited as showing the remarkable properties of a particular course of treatment. The slight exacerbations to which some men are subject who have previously had gonorrhœa, not due to fresh infection, but following excesses, often yield promptly to simple astringent injections; a very few injections of a corrosive-sUBLIMATE solution will almost surely check such outbreaks. Corrosive sublimate (1 to 10,000 or 20,000) also makes a very good, and I think the best, injection for chronic discharge.

Irrigation of the urethra, with a quart or more of warm solution, through a blunt nozzle held at the meatus, or, still better, through a catheter passed to the bulb, often gives satisfactory results in chronic urethritis; potassium permanganate (1 to 2,000), corrosive sublimate (1 to 20,000), or creolin (1 to 500) may be used in this way. The latter is quite irritating, and should not be used where there is any active inflammation. These irrigations may be repeated two or three times a week, an injection being used in the intervals, or the patient may irrigate himself every day. A sound passed occasionally may be found a valuable aid.

I am convinced, however, that by far the most rational method of treating chronic gonorrhœa is by means of local applications to the diseased mucous membrane through the endoscope. The advantage of ocular demonstration of the diseased surface, and of being able to observe directly the effect of treatment, is obvious. In October, 1887, I reported before the Suffolk District Society some cases of urethral endoscopy treated at the Boston Dispensary, and showed

some of the endoscopes designed by Dr. Hermann G. Klotz, of New York, and described by him in a very interesting article in the *New York Medical Journal*, November 27, 1886. (See Fig. 1.)

These endoscopes are straight, open tubes, of different sizes and lengths, made of coin silver, which allows of their being very thin and light, and is not affected by the solutions used in treatment. Any strong, steady light, reflected into the tube from a head-mirror, will sufficiently illuminate the urethra to admit of a close study of its pathological appearances. Having been passed down to the bulb, and the conductor removed, the endoscope is slowly withdrawn, giving opportunity for careful inspection of the mucous membrane and for treatment. The applications are made by means of a cotton tampon on the end of a wire, as large an endoscope as will pass the meatus should be used.

A more or less deep or livid congestion, with edematous swelling of the mucous membrane, dilated capillaries here and there, and a granular appearance in places, is the commonest condition. It may be nearly evenly diffused over the whole surface of the anterior urethra, but is generally more circumscribed, notably in the bulbous portion, but especially about the penoscrotal angle, where it is most marked, as a rule, according to my experience. The latter situation, or just anterior to it, is a common seat of stricture of large calibre, recognized by a rigid state of the mucous membrane, which is often associated with inflammation of the mucous glands of the urethra. When this condition is present, the inflammation is apt to linger here after it has subsided in the bulbous portion and elsewhere, and, when the general congestion has been partially reduced, the mouths of the glands may be seen as small points, each surrounded by a dark red or reddish-brown areola. In these cases of stricture recovery will almost surely be retarded, and it makes but little difference of how large calibre the stricture is. In one case a 38 (French) sound passed easily; yet a stricture was distinctly defined by a *bougie à boule*, and it proved a very troublesome complication.

Other abnormalities described by authors on endoscopy include variations in color and smoothness of the mucous membrane, thickening of the epithelium in stripes, erosions and ulcerations, polypi, papillomatous growths, etc. The latter, constituting the rare affection described by Oberlinger, of Dresden, as papillomatous urethritis, I have had an opportunity of seeing, through the kindness of Dr. F. M. Briggs, whose very interesting case is reported in the *Boston Medical and Surgical Journal*, October 24, 1889.

In endoscopic examination the light reflexes, minutely described by Grünfeld, sometimes a hindrance and sometimes an aid to the clearness of the view, should be carefully noted and taken into account, also

¹ Read at the meeting of the Surgical Section of the Suffolk District Medical Society, April 2, 1890.

Fig. 1. Klotz's Endoscope.

the effect on the color of the mucous membrane — paleness — produced by pressure of the end of the tube and of the cotton tampon.

In treatment, I have used nitrate of silver almost exclusively, and generally begin with a one per cent. solution and increase the strength gradually to ten per cent., if well borne. The cases which tolerate the stronger solutions seem to do better, as a rule. The applications are, of course, limited to the parts actually diseased, whereby the healthy parts are spared unnecessary irritation, and the stronger solutions, the quantity being small, may be safely used. A slight discharge for twenty-four or thirty-six hours, with moderate pain on micturition, is the only reaction to be expected. It would evidently be impossible to use an injection of anything like the same strength without setting up acute inflammation. The applications should be made every four to seven days, and, if thought advisable to use injections in the intervals, ordinary astringents may be prescribed, or a solution of corrosive sublimate (1 to 10,000 or 20,000); and sounds may be passed occasionally with advantage. A narrow meatus should be cut, strictures cut or dilated, and other complications treated according to indications.

The cases of stricture complicated with glandular disease are slow in their progress toward recovery, but generally do well in the end. The silver solution seems to work gradually into the mouths of the glands, and may help to promote absorption of the stricture tissue; this, I think, I have observed in one case. Klotz uses sulphate of copper where these glands are involved. These strictures are so resilient that very little can be accomplished by dilatation, and many patients object to being cut. Oberländer² treats them by forcible dilatation by means of his dilator, in which spreading blades may be opened to any extent. The dilatation is carried a little farther at each sitting, until the stricture is ruptured and the diseased glands split open, when applications of nitrate of silver (two to five per cent.) are sufficient to complete the cure.

Other diseased conditions are to be treated according to indications, and I will not go into details here. Ulcerations generally require strong applications or cauterization, polypi should be removed with the snare, and papillomata by means of the curette.

Fortunately, however, in most cases we have to do with a simple inflammation of the urethra. As a rule, they do well, and it is very satisfactory to see the mucous membrane gradually fading and assuming a normal appearance, and to hear the patient's expressions of gratification as he feels his disagreeable sensations passing away. The duration of treatment, of course, varies in different cases. In an ordinary uncomplicated case, a dozen sittings, covering a period of about two months, would probably suffice. Here is an average case:

CASE I. E. C., age twenty-one, began treatment with the endoscope August 13, 1888, after some preliminary treatment to diminish the discharge. First gonorrhœa a year and a half ago; duration six months. Second attack six months ago; discharge continues to date. Mucous membrane highly congested in the bulbous portion, gradually shading off anteriorly;

quite edematous in the middle portion. Solution of nitrate of silver, one per cent., applied. The history is simply that of gradual improvement in the appearance of the mucous membrane, the intense congestion fading out and leaving a nearly normal condition with simultaneous amelioration of subjective symptoms. A two per cent. nitrate of silver solution was applied August 17th; three per cent. August 20th, 24th and 27th; four per cent. August 30th; five per cent. September 5th; seven per cent. September 8th; and ten per cent. September 11th. The patient here suddenly broke off the treatment against my advice, and immediately plunged into excesses which he kept up almost uninterruptedly, without the least apparent disadvantage, until the following summer, when he had a slight exacerbation, which was easily controlled by a few injections of corrosive sublimate.

THE POSTERIOR URETHRA.

In passing the endoscope beyond the bulb into the deep urethra, great care should be observed to avoid injury to the delicate and inflamed mucous membrane held down against the end of the instrument, as it is, by powerful muscular contraction. Grünfeld recommends a hard rubber tube for this purpose, the edges not being as sharp as those of the metallic instrument; he passes it without a conductor, and is thereby enabled to keep the visceral end, under control of the eye, constantly in the axis of the urethra. A smaller endoscope should be used than in the anterior urethra, not larger than 24 F., according to Klotz.

The color of the mucous membrane is normally of a deeper red than in the spongy portion. With some practice and carefully guarding against expulsion of the tube by sudden and convulsive contractions of the external sphincter, the caput gallinaginis may be recognized as a bright-red rounded prominence in the lower part of the field with a crescent of dark-red mucous membrane above it. Bleeding is very easily excited in the deep urethra, which obscures the view and renders treatment less effective.

Pathological distinctions are less easily recognized through the endoscope than in the anterior portion. Grünfeld describes hyperamia, catarrhal swelling and hypertrophy of the caput gallinaginis, but Klotz thinks that differences in size of this organ may be due to individual peculiarity. Applications are made as in the anterior portion, but the solutions used should generally be milder.

Three years ago, Dr. E. L. Keyes, of New York, read before the American Association of Genito-Urinary Surgeons a valuable paper on "Deep Injections of Nitrate of Silver."³ He uses for the purpose a modification of Ultzmann's deep urethral syringe, the essential feature of which is a long, curved nozzle of pure silver with a pinhole opening in the end. (See Fig. 2.) He begins with a very weak solution, one grain to the ounce, and gradually increases the strength, rarely going above two per cent. Keyes thinks that most of the disagreeable results of this treatment, which have limited its popularity in the past, are due to passing the instrument too deeply into the prostatic urethra, and considers it important that the point of the syringe should just enter the membranous portion. Two or three minimis of the solution deposited here will diffuse themselves backward

² See "A Résumé of the Views of Dr. Oberländer, etc." by J. A. Fordyce, M.D., in Journal of Cutaneous and Genito-Urinary Diseases, January, 1889. There is also a detailed description of the treatment in Volkman's "Sammlung Klinischer Vorträge," No. 276, May 31, 1886, p. 14.

³ New York Medical Record, May 28, 1887.

over the mucous membrane and penetrate into the prostatic urethra. He prefers to inject before micturition, because otherwise the nitrate of silver is decomposed by the urine with which the urethral walls are bathed, but he allows the patient to urinate soon after, and then has him hold his water as long as possible and avoid straining. When there is much pus, however, he has the patient urinate first, and then injects a larger quantity (five minims), which will not be decomposed.

Keyes reports cases, successfully treated by this method, of acute and sub-acute gonorrhoeal cystitis; acute and chronic deep urethral inflammation; double relapsing epididymitis due to the latter; irritability of the bladder; the same due to enlarged prostate; oxaluria, prostatic neurosis and sexual weakness. He also recommends it in prostatorrhœa, spermatorrhœa, nocturnal emissions, and nervous impotence.

The results obtained by these deep injections are certainly, in many cases, among the most satisfactory in the treatment of urethral disease. Although not uniformly successful, they are generally so, and, if the patient is to be benefited, he will show signs of improvement after the first or second injection, as a rule. The treatment may be repeated every three or four days, and in inflammatory trouble a very few injections are generally sufficient. Impotence requires more and stronger injections.

I usually inject after micturition, and use five or six minims of the solution, beginning with one-half per cent. and increasing the strength gradually to two per cent. With a finger in the rectum, in the sulcus between the bulb and the prostate, the tip of the syringe may be felt as it enters the membranous portion, and a too deep insertion of the instrument thereby guarded against. It seems to me that this method of treatment is best adapted for gonorrhœal cystitis and other inflammatory affections of the prostatic urethra. A few cases will best illustrate the effects of the treatment.

CASE II. M. B., aged thirty-three, came to the dispensary August 6, 1887, with acute gonorrhœa, which was treated in the usual way, with diuretics and injections, until August 30th, when the discharge was diminished; but he reported that he had been seized a day or two before with frequent, painful and bloody micturition. In great distress at time of visit; it was impossible to hold water more than an hour, and a small quantity of purulent, bloody urine would then be passed with great pain, and followed by severe vesical tenesmus. A deep injection of nitrate of silver, one-half per cent., was given.

September 1st. Urinary symptoms entirely relieved, but he has pain in testicle; September 3d, testicle greatly swollen.

The patient had an acute epididymitis, which ran the usual course. He considered it a trifle, however,

compared with the suffering he had endured with cystitis. There was no return of urinary symptoms; the relief was prompt, complete and permanent. Whether the epididymitis in this case was the result of the injection, the nozzle of the syringe having been inadvertently pushed too far in, or whether it occurred in the ordinary course of the disease, it is impossible to say.

CASE III. J. H., aged twenty-four, on October 22, 1887, had gonorrhœa of six weeks' duration, with a copious, thin discharge, and for a week had been suffering with frequent micturition with blood at the end of the act, and followed by severe tenesmus. Deep injection of nitrate of silver, one per cent.

October 25th. Great relief for thirty-six hours, then return of symptoms. Injection repeated with a two per cent. solution.

October 27th. Much better. Injection repeated.

October 29th. Continued improvement. Micturition scarcely more frequent than normal. No tenesmus.

CASE IV. B. A., aged twenty-seven, August 21, 1888. First gonorrhœa four years ago; duration, a year and a half. Present attack of three months' duration; copious, purulent discharge. Very frequent and urgent micturition, with vesical tenesmus by day; no trouble at night. First half of urine passed is cloudy, second half slightly turbid. Deep injection of nitrate of silver, one per cent.

August 28th. Marked improvement. Micturition much less frequent. Injection repeated.

September 1st. Micturition normal. Discharge has stopped.

September 11th. Discharge has reappeared. No return of urinary symptoms.

In the treatment of various affections of the deep urethra I have obtained good results from irrigating the neck of the bladder with a solution of permanganate of potash. This is a perfectly safe operation, and subject to none of the risks associated with the deep injections of nitrate of silver. Uitzmann advises complete emptying of the bladder after irrigation; and in cases of acute inflammation, or when other solutions are used, it is probably a wise precaution; but I do not believe that any harm can come from leaving behind a small quantity of a mild permanganate solution. Moderate tenesmus, lasting a short time, is the only disagreeable symptom I have observed with mild solutions, and this is the exception. It has been my practice, at the suggestion of Dr. H. W. Cushing, to leave part of the solution in the bladder, and I have come to regard this as an important factor in the success of the operation. The fluid settles down into the neck of the bladder, as the patient walks about, and has an opportunity to exert its stimulating influence on the mucous membrane for a considerable time before it is decomposed by the freshly secreted urine. Potassium permanganate is rapidly decomposed in the presence of organic matter, and herein lies the safety of leaving this substance in the bladder, for the astringent and stimulating effect, which might become irritating if prolonged, is checked as soon as enough urine is secreted to decompose the solution.

The treatment is conveniently carried out by means of Uitzmann's large irrigating syringe and catheter. (See Fig. 3.) The syringe holds about five ounces of fluid; the catheter is a short metallic instrument, in-

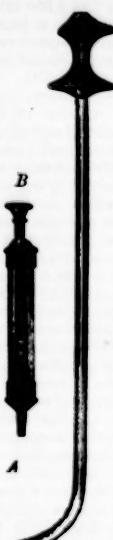

Fig. 2. Uitzmann's Deep Urethral Syringes.

tended to reach only as far as the back part of the membranous portion. A fountain syringe or siphon with an ordinary gum-elastic or soft rubber catheter may be used, but means should be provided for accurately measuring the amount injected. The catheter, having been filled with fluid and the air expelled, is passed just beyond the external sphincter, and four to six ounces of the solution, or as much as the bladder will comfortably hold, are slowly injected and allowed to run out again. This is repeated until the solution comes away with as bright red a tinge as it went in; then two or three ounces are injected into the bladder and left there, the catheter being removed. The patient is then allowed to go, being told to hold his water as long as he can without positive discomfort. I usually begin with a 1 to 4,000 or 5,000 solution, and gradually increase the strength. Solutions stronger than 1 to 2,000 are not as a rule well borne, and those weaker than the first-mentioned are so rapidly decomposed as to accomplish little. Solutions of a strength of 1 to 3,000 and of 1 to 2,000 are the most useful.

After employing this method in two or three cases of prostatorrhœa with success, it was tried in several cases of cystitis and in one case of spermatorrhœa.

Like every other treatment it sometimes fails, but improvement may be expected and entire relief of symptoms has followed in many cases. If good is to result it is soon apparent and a few injections only are necessary, as a rule, to bring about the desired effect. The following are a few illustrative cases.

CASE V. A. C., age forty-six, in very poor general health, came to the dispensary September 18, 1888, with gonorrhœa of two weeks' duration; thin, purulent discharge, chordee, and frequent, urgent, painful micturition with vesical tenesmus. He was treated with diuretics and tonics, with only temporary relief of the urinary symptoms, until October 2d, when the bladder was irrigated with a solution of potassium permanganate 1 to 4,000, two ounces being left in.

October 6th. Relief for a few hours after irrigation, but vesical symptoms have now returned. Irrigation repeated with a 1 to 3,000 solution.

October 9th. Improvement. Irrigation with a 1 to 2,000 solution.

October 13th. Urinary symptoms entirely relieved.

October 20th. Micturition normal.

CASE VI. A. R., age seventy, with no venereal history, complained, September 27, 1888, of frequent micturition with severe tenesmus and blood at the end of each act. Urine nearly clear. Small amount of residual urine. Prostate moderately enlarged. He was treated with diuretics until October 9th, when there was no improvement and he was irrigated with a

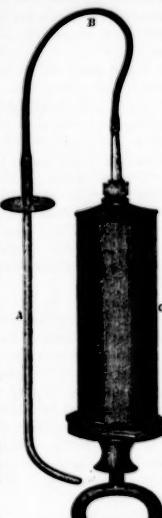

Fig. 3. Ulzmann's Syringe-Catheter.

permanganate solution, 1 to 3,000, two ounces being left in the bladder.

October 13th. Great improvement. Irrigation with a 1 to 2,000 solution. The patient did not return, but was seen a year later and said that he made a rapid and complete recovery after the last visit. The cause of the vesical symptoms in this case is obscure.

CASE VII. L. E., age twenty-two years, no venereal history.

October 18, 1888. For six weeks has been troubled with frequent and painful micturition with vesical tenesmus; occasionally passes a small amount of blood. Urine turbid; when passed in two glasses the last half is slightly tinged with blood and contains whitish clumps which, under the microscope, prove to be only fibrin. A few days later the urine contained a heavy sediment of pus, most of which was passed toward the end of micturition, and a little blood; albumen one-quarter per cent. Prostate slightly enlarged and moderately sensitive. Was treated with diuretics with some improvement in subjective symptoms and in character of urine, but none as to frequency and precipitancy of micturition, until October 27th, when the bladder was irrigated with permanganate solution 1 to 3,000 and some fibrinous shreds washed out. Two ounces of the solution were left in the bladder.

October 30th. Marked improvement. Can hold water longer. Urine clearer. Irrigation repeated with the same strength of solution. He improved rapidly after this without further local treatment. He was seen a year later and said that his recovery was complete and permanent.

CASE VIII. F. G., age twenty-one, tall, well built and apparently in perfect health, was first seen February 29, 1888, and gave the following history. First gonorrhœa a year ago; second, three months ago, duration six weeks. Ever since this last attack he has had a discharge after micturition and defecation of a whitish,ropy substance. He says that sexual desire and power are diminished, but does not feel in the least nervous or anxious about his condition. General health perfect.

The patient urinated in my presence and immediately afterward passed, with very slight effort, about a teaspoonful of the substance described above which, under the microscope, proved to be pure semen. He was given pills of iron, ergotin and strychnia and was not seen again until September 12th.

He then reported that he had taken the pills only three weeks and the discharge of semen had continued uninterruptedly, although he could sometimes prevent it by avoiding straining after evacuating the bladder or rectum. His general health continued good and he had regained sexual power and desire. He again produced some semen for examination, although not quite as much as before, and it showed the same characteristics under the microscope. He was directed to resume the pills and the neck of the bladder was irrigated with a solution of potassium permanganate 1 to 5,000, two ounces being left in. The irrigation was repeated as follows, with a gradual diminution in the amount and frequency of the discharge: September 17th, 1 to 3,000; September 21st, 1 to 2,000; September 24th, 1 to 1,500; September 28th, 1 to 1,000.

October 3d. The last injection was followed by severe pain and urgent desire to urinate which was resisted for an hour, and then micturition was very painful, especially at the end, and accompanied with

the discharge of a thick reddish substance in clumps (permanganate). Very little pain after this. No seminal discharge. Local treatment suspended. Pills continued.

This patient has been recently seen and reports that there has never been the least return of the seminal discharge and he has remained well in all other respects.

GONORRHEA IN WOMEN.

Gonorrhœa in women has been a good deal written about in recent years and there is great difference of opinion as to pathology, especially in regard to the relative frequency with which different parts are invaded. Some authorities think that urethritis is present in every case of gonorrhœa, others consider it as an occasional complication only. Bartholini's glands are commonly, or rarely, involved, according to the views of one writer or another. Some maintain that the disease rarely extends beyond the cervix, while others, Sinclair for instance, of Manchester, Eng., following Noegerath, regard implication of the uterus and its appendages as the great danger and believe that it will almost surely follow if the progress of the disease be not promptly checked.

As for the vagina it probably always has been and still is commonly looked upon as a favorite seat of gonorrhœa. Yet Sigmund⁴ and Steinschneider⁵ of Neisser's clinic in Braslau, declare that gonococci do not settle upon the mucous membrane of the vulva or vagina; and Sinclair says "it is still a question whether there is any such thing as gonorrhœal vaginitis. The vagina seems to be the last portion of the genital tract, from the uterus downwards, to become affected, and the first to get well under any suitable cleansing process."⁶ He thinks, however, that the vagina in children and young girls may provide a more favorable breeding ground for the micro-organisms. Bunn⁷'s researches furnish strong evidence of the non-existence of vaginal gonorrhœa. He cut out bits of suspected mucous membrane and examined them microscopically with negative result, and also kept gonorrhœal pus in direct contact with the vaginal wall twelve hours without setting up vaginitis. The discovery of gonococci in the secretion about the vulva or in the vagina, of course, does not prove that the vulvar or vaginal mucous membrane is affected, for they may have come from the urethra or cervix.

In most that has been written on treatment, a good deal of space is taken up in detailed descriptions of elaborate and more or less severe methods of treating the vagina — scraping, scrubbing, cauterizing and packing. It seems to me that we should satisfy ourselves that gonorrhœal vaginitis really exists before resorting to measures, as routine treatment, so heroic and so difficult to thoroughly carry out. I believe that frequent douching with fairly strong antiseptic solutions will be found efficient, as far as the vagina is concerned, in a large majority of cases.

The urethra should be carefully attended to, for here the disease is apt to linger. Copaiba and other internal remedies used in the male may be employed. Skene⁸ advises injections of nitrate of silver and sul-

phate of zinc, with suppositories of iodoform or bis-muth. Finger,⁹ of Vienna, applies, through an endoscope, tincture of iodine or solution of nitrate of silver, two to five per cent. Aubert,¹⁰ of Lyons, gives injections of nitrate of silver, or passes the solid stick rapidly into the urethra. Erand,¹¹ of Lyons, curettes the urethra, and then applies nitrate of silver. Cullingworth¹² of St. Thomas' Hospital, London, passes into the urethra a sound wound with cotton and dipped in strong carbolic acid.

The three surgeons last mentioned treat the cervix as they do the urethra, that is, with solid nitrate of silver, curette, and strong carbolic acid respectively, carrying the applications up to the fundus, if necessary. Sinclair injects pure tincture of iodine into the uterus.

Within the last year improved facilities have been provided for the treatment of women in the Genito-Urinary Department of the Boston Dispensary, and more attention has been paid to patients of this class than before. The treatment has been more or less experimental, but many of the cases have shown marked improvement. It has been found difficult, however, to induce the patients to come regularly and to persevere in treatment after they have improved so far as to be free from actual discomfort. The scientific value of the records, therefore, is not as great as could be wished. By way of giving an outline of the treatment I have followed, and in the hope of exciting criticism and discussion, I report the following case:

CASE IX. Julia B., age twenty-eight, on September 12, 1889, had a discharge of two months' duration. She had had more or less leucorrhœa for ten years. Physical examination showed the following condition: Considerable purulent, urethral discharge; also a vaginal discharge and a copious, glairy, muco-purulent discharge from the cervix uteri, with erosion of the os. Microscopic examination, by Dr. E. M. Greene, showed numerous gonococci in the urethral and cervical discharge, but none in the vagina.

The following method of treatment was adopted: The vagina was first thoroughly irrigated with a solution of corrosive sublimate 1 to 5,000, and the vulva carefully cleaned with the same solution. Then, a speculum having been passed, theropy discharge clinging to the os was wiped away, and the cervix cleaned out as thoroughly as possible. An application of carbolic acid (95 per cent.) was then made to the cervical canal as far as the internal os, by means of a sound wound with cotton, and also to the erosions about the external os. The speculum was then slowly withdrawn, and any secretion seen on the vaginal walls was wiped off with a swab wet with the sublimate solution. An ordinary, small-sized, soft rubber catheter was next passed into the urethra, and this canal was irrigated with the 1 to 5,000 corrosive sublimate solution. A suppository, or short bougie, of iodoform was then inserted into the urethra and held there until it melted. At home the patient used as a douche, twice daily, a solution of zinc sulphate and alum, two grains of each to the ounce. This was changed later to a four per cent. solution of boric acid.

The local treatment was repeated three times a week, and at the seventh visit there was still a slight urethral

and cervical discharge, but the gonococci had disappeared. The treatment was then interrupted by menstruation, and at the next visit was suspended, the urethral discharge having stopped and the pus having disappeared from the cervical discharge. The erosions about the os were entirely healed.

The patient was seen again January 2, 1890, and was found to have a slight urethral discharge containing gonococci. There was also some vaginal discharge or leucorrhœa, and a moderate amount of colorless, transparent,ropy, cervical discharge. The os looked perfectly normal. There were no gonococci in the vagina or cervix.

Corrosive sublimate irrigation of the vagina and urethra was resumed. The gonococci disappeared from the urethra in a short time, but the irrigations were kept up, at irregular intervals, for several weeks. When occasionally a slight, thin secretion could be, with difficulty, pressed from the urethra, it was examined under the microscope, but always with negative result. At the last visit there was no trace of discharge.

It is probably a wise precaution to keep up the irrigation, at more or less frequent intervals, for some time after the urethral discharge disappears. The patient should be directed to hold her water as long as possible before the visit, in order that any trace of discharge may be discovered.

EPIDEMIC INFLUENZA AND INSANITY.¹

BY ARTHUR H. HARRINGTON, M.D., OF DANVERS.

WHEN I had the honor of receiving an invitation from the chairman of the Medical Section to present a paper at this time, it occurred to me that it would be pardonable if I referred to some cases which I reported a few weeks ago at a meeting of the South Essex District.

These cases, which are instances of insanity developing together with or after an attack of the influenza, may be of interest to you, considered as one of the phases of the recent epidemic. In addition to the original paper, I have, through the kindness of a number of medical gentlemen, been able to obtain some useful material upon this subject, so that we shall have for our consideration the observations of others rather than mine alone.

In looking over the history of the various epidemics of influenza, we find careful descriptions of the thoracic, the abdominal, and the nervous types of the disease,—under the latter are included the general nervous or cerebral disturbances. Now, such cerebral disturbances as headache, insomnia, somnolence, delirium, etc., receive attention; but, in the literature which I have been able to consult, the statements touching upon the purely mental disturbances or psychoses are of a most general character. And this is my reason for presenting this subject somewhat in detail, and mainly from a clinical standpoint.

Before taking up these cases, if you will allow me, I should like to remind you of the limitations to which one is subject in attempting to assign the cause or causes of insanity in a given case. Probably in this class of affections the predisposing causes play a more

prominent part than in almost any other. This fact is often overlooked, no doubt, and many times what are put down as the prime causes are really only the secondary or exciting. Moreover, it is rarely that a single cause can be fastened upon and held responsible alone for the mental disturbance.

These considerations have been kept in view in studying these cases, as complete a previous history as could be gained was taken of each, and it was found that, of the cases at the Danvers Hospital, with one exception,—and in this instance the previous history was not ascertained,—there existed predisposing causes, congenital and acquired, but it seemed quite certain that the attack of influenza, with its febrile symptoms, its tendency to cause great physical and nervous depression, was the final weight which turned the scale.

It was found that a classification based upon the previous histories could be made, into which the cases fall quite naturally. This classification is not an essential one, but is made to facilitate our easy comprehension of the cases.

I will state that I am indebted for the data of the female cases to my colleague, Dr. M. A. Jewett.

CASES I and II are instances in which the patients had been insane, but had recovered. An attack of influenza seems to have been the exciting cause of another attack of insanity. Case I, a female, aged sixty, has had two attacks of acute mania, treated at the Worcester and Danvers Hospitals. She was well mentally and living with her family when attacked with the influenza, January 10th. She very soon became restless, confused, passed into a maniacal state, and was admitted to the Danvers Hospital ten days later, where she died after a few days from exhaustion. Case II, a female patient, aged twenty-three, has had one attack of acute mania, from which she recovered. She was attacked with the influenza, and soon afterwards maniacal symptoms appeared. She was admitted to the hospital January 9th, where she continued in an acutely maniacal state for four days. At the end of this time her maniacal symptoms subsided and she became quite rational. A month after admission she appeared to have made a complete recovery. This attack must be regarded as presenting all the motor excitement of acute mania; but the delirium which the patient exhibited was more like that of an acute febrile disease. Attention is called in this case to the prompt recovery, which began with the subsidence of the acute bodily symptoms.

CASES III, IV, V and VI are instances in which there had existed, for longer or shorter periods, enfeebled physical conditions from various causes, and which were very likely preparing the way for a mental breakdown, but in which the influenza seems to have been the exciting cause of the attack of insanity.

CASE III, a female, aged thirty, has had symptoms of phthisis for two years, and last July had a severe attack of pleurisy, which weakened her very much. In addition to these debilitating causes she had been nursing her child for twenty months. Her friends state that she was completely run down, but never showed any signs of insanity until attacked with "La Grippe," when she became restless, sleepless, then maniacal, refused nourishment and resisted attentions. She died from exhaustion and capillary bronchitis nineteen days after admission to the hospital. In this instance doubtless, phthisis, pleurisy and prolonged

¹ Read before the Massachusetts Medical Society, June 10, 1890, and recommended for publication by the Society.

lactation were contributing causes to an attack of insanity, which was precipitated by the additional depressing effects of the influenza.

CASE IV, a domestic, aged twenty-five, has been feeling "poorly," nervous and debilitated for two months, and left her place on this account. She was attacked with the influenza, and was sent to the Boston City Hospital, where she became frightened, thought some one was going to kill her, and tried to jump out of the window. She was sent to the Danvers Hospital, where she was restless and stubborn for a time. At the end of a month she was better, though somewhat confused and dull. She was discharged four months after admission. Her progress had been slow, but steady, and she left the hospital with a fair chance of making a complete recovery.

CASE V, a male, aged thirty, a native of France, has been in the country a few months. When attacked with the influenza he developed hallucinations of smell, detected a strong odor as of some poisonous substance on his pillow, thought the landlady was attempting to poison him in order to get his money. He became frightened. In order to attract the police and get protection he broke his window, shouted for help, and fired a pistol into the street. He was committed to the hospital December 30th. He was weak and emaciated, and aside from the pulmonary symptoms of the influenza, he was thought to be suffering from phthisis. He was quiet and polite on admission, but during the evening attempted suicide. The next morning he regretted his action, but confirmed the delusions mentioned above. As he recovered from the influenza the hallucinations of smell disappeared, and two weeks after his admission, while he recognized his actions and many of his ideas as foolish, yet he was not able to dispossess himself wholly of the belief that his landlady had attempted to poison him. This belief remains like a "fixed idea," and it is not unlikely that in this instance the attack of influenza was the exciting cause of a mental disorder which may become chronic.

From a psychological point of view this case is very interesting, as showing the apparent origin of the delusional ideas in the hallucinations of smell,—these latter or at least disorders in olfactory sensation and perception being not an uncommon symptom connected with the influenza.

CASE VI, a gentleman, aged sixty, was thought to have had a slight apoplectic attack two years ago. His physical health from that time has been poor, and he has been subjected to severe mental strain and worry growing out of business affairs. He was much prostrated by an attack of influenza, and did not gain strength again, and after three weeks he began to show signs of mental derangement, and was sent to the Danvers Hospital. This case proved to be an excellent example of acute confusional insanity, a form which will be referred to again. The patient's death, which occurred in three weeks after admission, was due to exhaustion and capillary bronchitis.

CASES VII, VIII and IX were individuals evidently belonging to a well-known class; the characteristics of its members are, that they are the possessors from birth of a bad physical organization and are of a low grade of intellect. Such persons often break down mentally early in life, from comparatively slight causes.

CASE VII was a boy, aged seventeen. His mental

disorder was that of acute confusional insanity. He made a rapid and complete recovery, and was discharged in a few weeks.

CASE VIII. This was another instance of acute confusional insanity, in a young woman aged twenty-five. Her mental symptoms cleared up to a great extent, but she could not be said to have recovered fully when discharged. In the last two cases the mental disorder developed while the subjects were suffering from the acute effects of the influenza, and with improving health the mental condition improved also.

CASE IX. In a colored woman, aged twenty-five, an attack of the influenza was followed immediately by acute mania. She was admitted to the hospital, and died very suddenly. A post-mortem revealed cardiac thrombosis.

CASES X and XI taken together are interesting. At various times they had been given to the excessive use of alcoholics. An attack of the influenza seems to have given rise to certain mental symptoms which are sometimes observed after prolonged drinking. Case X, a male, aged fifty-one, has been a periodic drinker for years. When getting over a drinking spell he would almost always have a period of profound depression, and would be suicidal. During one of these periods, in 1886, he came near destroying himself by cutting his throat, and was at the Danvers Hospital for a time. He was admitted again January 1, 1890. The statement was that he had been working steadily, for several months, up to the time of his attack of influenza, and his friends asserted that he had not drunk of late. While suffering from the influenza he grew sleepless and despondent, took no nourishment, then became violent and suicidal. After coming to the hospital he remained greatly depressed. His death occurred after a few days from capillary bronchitis and cardiac complications. The point to be noticed in this instance is that an attack of great mental depression with suicidal tendency, exactly like the attacks which followed his periods of excessive drinking, developed simultaneously with an attack of influenza.

CASE XI. A young man, aged twenty-seven, has been in the habit of drinking a good deal, but has never been affected by it mentally. Was attacked with the influenza and confined in the house for ten days. During this time he had no liquor, but hallucinations of hearing began to trouble him, and disturbed him to such an extent that he was sent to the Danvers Hospital. The committing physicians also stated in their certificate that they thought his mental trouble due to the "Grippe." As soon as this patient began to improve physically, his hallucinations wholly disappeared. Hallucinations of hearing, as we all know, are a very common result of prolonged drinking, but this patient seems never to have suffered from them until attacked with the influenza. In this instance the use of alcoholics had probably made the conditions favorable for the development of hallucinations, and the acute illness seems to have been their exciting cause.

In a recent report of eleven cases of insanity after influenza, by Kraepelin, he cites a case in which a man, who had been addicted to alcoholic excess, developed a typical delirium tremens when attacked by the influenza.

CASE XII, the only one of the cases seen at the

Danvers Hospital, whose previous history was not ascertained, and in whom no predisposing cause of insanity was found, was a case of acute confusional insanity. He made a complete recovery in a few weeks.

In making a few general remarks upon these twelve cases, I will say that the physical as well as the mental symptoms were of a very marked character. The patients, when admitted, had the facies of an acute exhausting disease; there was the great depression of the physical forces and the acute bronchitis with a profuse muco-purulent expectoration which characterized the epidemic disease. As for the mental symptoms, out of these twelve cases, four were excellent examples of acute confusional insanity, and six of the remaining cases presented some symptoms which would remind one strongly of that type.

By acute confusional insanity is meant a form which resembles acute mania, and, as far as outward appearances go, might readily pass for acute mania, but at the bottom of which there is no emotional disturbance as in acute mania, the conceptional sphere is dimmed, consciousness is blurred, and patients recovering have a crude recollection of their condition. When hallucinations predominate, this is called by some "acute hallucinatory insanity." This form most often develops on the basis of acute, exhausting and depressing diseases, the very factors which were present in the cases which have been cited, and which would account for their general leaning towards the type of acute confusional insanity.

Of these twelve cases, those which recovered or improved did so promptly as soon as the physical condition improved. The mortality in the twelve cases named was large, and was due to the exhausted condition of the patient, together with cardiac and pulmonary complications.

The study of these twelve cases led me to a desire to learn the experience of other hospitals during the recent epidemic. Accordingly, I sent out a number of circular letters, and I received replies from the superintendents and medical officers of twenty-two institutions. I desire to express my thanks for their courtesy in answering my questions so promptly and carefully.

The letter comprised six questions, and the replies were both negative and affirmative, and I will give the sum of them very briefly:

First Question. — In how many cases of insanity has the influenza been regarded as the exciting cause?

In ten hospitals out of the twenty-two no cases had been observed. In the remaining twelve hospitals the aggregate number of cases admitted, thought to be due to the influenza as their exciting cause, was thirty-six.

Second Question. — In how many of these cases has the influenza been the only assignable cause? The answer was sixteen out of the thirty-six.

Third and Fourth Questions. — How many cases have recovered, and how many have died? Twelve had recovered and two had died out of the thirty-six cases.

Fifth Question. — What forms of insanity have been observed? I give the diagnoses, of course, just as I received them, and for convenience will include here the twelve cases of the Danvers Hospital. So that out of forty-eight cases, seventeen were acute mania; fourteen acute melancholia; five primary confusional

insanity; two each of simple mania, simple depression and delusional insanity; one each of acute delirious mania, acute febrile delirium, acute dementia, senile mania, apoplectic dementia and alcoholic dementia.

Sixth Question. — Have the mental symptoms as a general thing presented any peculiar features due perhaps to the influence of the epidemic disease? The answers to this question quite generally bore out some observations of my own. Among them I will quote the following:

Dr. C. M. Hay, of the State Asylum at Morris Plains, says, "Generally the insanities in these cases have been of a very marked type, but whether this was due simply to the exhaustion in which the mental affection found them or was connected with a specific toxæmia I cannot say." Dr. Cowles of the McLean Asylum states, "I do not know that the mental symptoms have presented any notable peculiarity except the tendency to prompt recovery as if upon the abatement of some debilitating or depressing influences."

Another question which might have been asked, namely: What effect has the influenza had upon those already insane when attacked by it? was suggested afterwards by a report of some cases by Dr. Paine of the Westborough Homeopathic Hospital and which appeared in the *Boston Herald* of April 24th. I have been referred by Dr. Paine to this report, so I take for granted that he was correctly quoted. Dr. Paine, you may remember, reported some cases suffering with chronic forms of insanity who recovered mentally after an attack of the influenza, to which he attributes their recovery.

Unfortunately of the thirty per cent. of the insane population at Danvers Hospital who suffered from the influenza none seemed to be cured by it. In fact the mental symptoms were augmented rather than diminished even remarkably so in four cases.

Dr. Lyon, of the Bloomingdale Asylum, says, "I may add that I have seen no such remarkable cures from chronic insanity or any other form, effected by the 'grippe,' as I have read of." Dr. Park, of the Worcester Hospital, says, "We have had no cases of recovery from chronic mania due to 'grippe.'"

CONCLUSIONS.

This paper has not aimed to gather the statistics of the relation of the recent epidemic of influenza to insanity. This would be a difficult and uncertain task. It is quite likely that in many cases attention was not given to the subject, and the most that can be learned will probably be found in the annual reports of the institutions when they shall be issued. But taking the cases of the Danvers Hospital and those reported from other hospitals, we have forty-eight cases in which an attack of the influenza was followed immediately or in a short time by the development of a psychosis. In thirty-one cases the influenza acted as an exciting cause to insanity, predisposing and other exciting causes being clearly made out. In seventeen cases the influenza was the only assignable cause of insanity. I incline to the belief that if the antecedents of these seventeen cases could be thoroughly analyzed, this number seventeen, in whom no predisposing causes were known, would be diminished and that we might approach nearer a conclusion made by Kraepelin, namely: that the influenza alone is not sufficient to occasion the development of a psychosis.

Of the total forty-eight cases, sixteen recovered.

Considering that in hospitals the average number of recoveries in new cases is only from fifteen per cent. to twenty per cent., the recovery of thirty-three per cent. of these cases is worthy of remark.

Cases of insanity excited by the influenza have shown a greater tendency to prompt recovery or improvement than is usual in recent cases. In most instances the improvement has been coincident with the abatement of the acute bodily symptoms and the return to physical strength and health.

Finally, out of these forty-eight cases, while I cannot include them all in a classification, yet it is quite easy to recognize three main groups, namely:

(1) Cases of simple depression and hypochondria. Many such instances were no doubt seen by those in general practice during the epidemic, but in which the mental disturbance did not proceed far enough to demand hospital treatment.

(2) Cases in which the emotional disturbance was carried farther than in the first group, resulting in acute forms of mania and melancholia.

(3) A considerable proportion of cases which developed on the basis of bodily exhaustion and depression of the nervous forces, namely: the cases of delirious mania, febrile delirium, and especially those of acute confusional insanity, which appears to me to be the type towards which the symptoms in many cases have inclined.

HYALINE-FIBROID OVARIAN DISEASE.¹

BY RENÉE GIBBS, M.D.,
Professor of Pathology, University of Michigan.

In January of this year I published a paper in the *Boston Medical and Surgical Journal*, on the "Origin of Ovarian Cysts." Since then I have examined a number of ovaries, and can now add something to the facts stated in that paper. I then gave three causes for the origin of cysts in the ovaries: (1) an overgrowth of normal tissue, supposed to be of embryonic character; (2) dilatation of Graafian follicles; (3) Hyaline degeneration of the ovarian stroma. Further investigation inclines me to think that this latter form is a much more frequent cause of ovarian disease, at any rate in young patients, than the other two; and I wish to say a few words on this peculiar change. I have called it hyaline degeneration; and from the examination of a large number of ovaries removed during life, I am convinced that a large majority are affected by this change. The term hyaline degeneration conveys no clear impression to the mind of what the change is, further than that it is a homogeneous material into which the normal ovarian stroma is trans-formed.

It is important, therefore, to find out the nature of the new formation, and then, if possible, its preventive or cure. To establish its precise nature, I have made a number of experiments with reagents, with a view to finding out its chemical nature and the normal tissue to which it corresponds. I am now satisfied that it is not a degeneration, in the strict sense of the word, but a new formation of fibrous tissue of a peculiar character. I will not give an account here of the numerous experiments I have made, as it would prove tedious, but will state their results. In the first place, we all know that in whatever condition white fibrous

tissue is found normally in the human body, it has always associated with it connective-tissue corpuscles; and when this tissue is in a young, growing state, then these corpuscles will be very numerous. This is also seen in rapid new growths of fibrous tissues, such as keloid, where the connective-tissue corpuscles are distributed in enormous numbers among the rapidly growing fibrous tissue. This is exactly what is found in the new growth in the ovary. At first, narrow, sinuous bands of fibrous tissue appear in the ovarian stroma. They become larger and many in number, always having the same peculiar, tortuous arrangement. Between these bands are numbers of branched connective-tissue corpuscles, closely applied to the fibrous tissue. The chemical reaction of this new growth is similar to that of white fibrous tissue growing rapidly under other conditions; and the relation of the connective-tissue corpuscles to it is also seen in other normal and abnormal conditions. I consider, therefore, that I am justified in calling this a growth of fibrous tissue of a peculiar kind.

Now this fibrous change is not peculiar to the ovary. I have found exactly similar conditions in the lungs in tuberculosis, and in slow-growing carcinoma, and an almost similar change in slow-growing sarcoma. These cases were all of slow growth. The lungs were invaded by reticular tubercle; and the disease had existed for two or three years. In all there was chronic irritation. Now, what we want to know is, What caused a new growth of fibrous tissue that, in the case of the ovary, could break down to form a cyst. I must here state that in all these formations the new growth became extensive, and being probably of low vitality, with a deficient nutrient supply, the central portion, after a time, broke down, and formed a cavity, this filled with fluid, as all cavities in the ovary are prone to do, and gradual dilatation took place, ending in the formation of a large cyst.

In a state of nature, unfettered by civilization, the human female was probably intended to conceive and bear young as other animals do; and in this way the ovary could perform its function at periodical intervals with intervening periods of rest, we have, however, altered all this. A large majority of women pass through that period of their lives when their sexual organs are in their highest functional condition, without there being any opportunity for the exercise of these functions. This, of itself, would not prove prejudicial to health; but when un congenital employment and surroundings are added, is it any wonder that something goes wrong?

Women at the present time are pushing more and more into conditions of life which are eminently unsuitable to them, but they are forced to do so under existing circumstances. Any one who has lived amongst people in a semi-savage state, knows how little the females suffer from diseases of their sexual organs and what an extremely simple matter parturition is. But take the everyday life of a working-girl who has, in many cases, to be on her feet all day, often in a close, unhealthy atmosphere, or under many other conditions all more or less unhealthy — this going on during the menstrual period, what is the result? A condition of anemic dyspepsia; and after this has existed some time, comes leucorrhœa, bearing-down pains, pain in the back, etc. Now, if the patient be examined in an early stage of this condition, it will generally be found that one of the ovaries is enlarged and tender; and in

¹ Read before the Michigan State Medical Association, Grand Rapids, June 19, 1890.

the majority of cases, it will be the left. The pain can often be traced to this ovary, and will be found to extend down the front of the thigh, or in towards the spine in the lumbar region. This condition of things seem to be brought about by an unhealthy condition of life reacting on an organ in full functional activity, but called on to perform that function continuously and without that period of rest intended by nature.

This is the acute stage, and may exist for a long time, but is certain, if not relieved, to become chronic, that is, to produce structural change. We know that, after a time, an acute disease becomes chronic, and produces change in an organ, and that these changes vary with the organ and the exciting cause. It is therefore quite probable that a long-continued irritation, acting on such an organ as the ovary under the conditions I have named, would be likely to produce those changes which I have found in nine-tenths of the ovaries I have examined.

The organs are also sometimes subjected to abnormal excitement, both in the married and unmarried, which I need only allude to here, but which must be very prejudicial to their well-being. In a large outpatient practice in London I had abundant opportunity for studying these cases, and I found no difficulty in curing them when taken in time. My treatment was first for the dyspepsia, then the anæmia, and concurrently with this counter-irritation over the affected ovary. I had many cases under observation for years with no return of the symptoms.

I have lately received ovaries from Dr. Minar of Bay City, Dr. Manton of Detroit, and a number of others, and they all show this same fibrous change. The ovary received from Dr. Minar has, in addition, a large cyst lined by columnar epithelium, which I am inclined to think is caused by the inclusion of a portion of the fallopian tube in the hypertrophic growth.

The ordinary pathological change, then, that is found in ovaries removed during life, is of the nature described. The same change occurring in other conditions show that the cause is a chronic irritation. This irritation, in the case of the ovaries, is probably of nervous origin, and is brought about by an abnormal condition of the patient and her surroundings. It also begins in an acute form, which, from an experience extending over a number of years among a class of women peculiarly liable by their work and everyday life to this affection, I have found to be easily curable if taken in an early stage.

REPORT ON OBSTETRICS.

BY CHARLES M. GREEN, M.D.

THE INFLUENCE OF INFLUENZA ON THE FEMALE SEXUAL ORGANS.

WHEN epidemic influenza may again haplessly prevail, the medical profession will be better informed as to its probable effects in causing or modifying other phases of disease. Much has been, and more will be, written on the immediate and remote results of influenza; and from many observations will be deduced, doubtless, facts of interest and value.

MÜLLER¹ (Munich) has observed fifty-one cases of influenza in women, three of whom were pregnant; and his paper is an interesting contribution to the sub-

ject. Of the forty-eight cases of influenza in the non-pregnant, Müller believes that the genital affections found present when he saw them were induced by influenza in forty-six instances: in one case, the sexual organs appeared to be in no way affected; and in one other case the epidemic influenza on these organs was undecided.

The important symptom by which the epidemic influenza manifested itself in the non-gravid was profuse metrorrhagia, which was characterized by its long continuance and great resistance to ordinary measures for relief. The bleeding was accompanied by swelling and sensitiveness, and enlargement of the uterus.

In the three gravid cases affected with influenza, pregnancy was interrupted in two instances: in the third case pregnancy was not in the least affected by the disease. The first case, in the eighth week of her fourth pregnancy, took sick with mild symptoms of influenza, and with the appearance of the first symptoms was seized with profuse uterine hemorrhage which resulted in abortion. The bleeding was so severe from the beginning, that when seen by Müller she showed symptoms of collapse; and the hemorrhage continued profuse for several days in spite of energetic treatment. Other causes of the abortion were sought for; but nothing could be found to account for it in the history of the three preceding weeks. The ovum presented no abnormality.

The second case was in the eighth month when seized with violent symptoms of influenza: there was cough, but not of such severity as to have caused premature labor by concussion. With the invasion of influenza uterine contractions set in which lasted four days and finally resulted in the expulsion of the fetus in spite of treatment to prevent it. The loss of blood was considerable. The influenza had considerably diminished in intensity by the end of four days, but continued for eight days after delivery. In other respects the puerperium was normal, and involution was not retarded.

Both of these cases were multiparous; but the third case was that of a primigravida, who, while in the third month, had a severe attack of influenza with fever, bronchial catarrh, and almost continuous, severe cough. The sickness lasted eight days; but the pregnancy was in nowise affected.

MEASLES IN PREGNANCY.

The occurrence of measles during pregnancy is so infrequently observed that the following case, reported by LOMER² (Hamburg), is of interest:

A primigravida, aged twenty-two, who had always been healthy and had never had measles as a child, expected her delivery in the middle of July. On June 7th, while a severe epidemic of measles prevailed in her town, she was suddenly seized with chills, cough, fever, burning in the eyes, and diarrhoea. Next day labor supervened, and in seven hours she was spontaneously delivered of a premature, living child. When seen the next morning, the eruption of measles was found on both mother and child: on the mother, distributed over the whole body; on the child, on forehead and chest. On the fifth day the mother was taken with pneumonia, from which, however, she recovered after a long sickness: the child died in four weeks of intestinal catarrh.

Cases of measles complicating pregnancy have been

¹ Centralblatt für Gynäkologie, 1890, No. 17.

² Centralblatt für Gynäkologie, 1889, 48.

seldom described, and the text-books have little to say on the subject. Lomer quotes from an article by GAUTIER,² who was able to collect from the literature only eleven cases, of which most were of ancient date and defectively reported. Among these eleven cases, in six was the mother infected during the last month of pregnancy, and in all six cases the infants were said to have been born with the eruption of measles, or the exanthem appeared soon after birth. On the other hand, in a case observed by Gautier, the infant was born free from the eruption, which moreover did not appear subsequently, although the child was suckled by the mother. In the other four cases collected by Gautier, the infection led to interruption of the pregnancy, and two mothers died.

RELAXATION AND RUPTURE OF THE PELVIC ARTICULATIONS.

Under this title REMY⁴ describes two cases observed by him. In the first case, a relaxation of the left sacro-iliac articulation occurred in the spontaneous labor of a very strong girl. The lesion manifested itself by acute pain when the patient attempted to get up: a supporting girdle gave great relief; but a number of months were required for permanent cure. [This case is not without medico-legal interest as showing that injury to the pelvic articulations may occur in non-instrumental deliveries.]

In the second case separation of the pubic symphysis occurred with a loud cracking sound during forceps extraction of a large child through a generally contracted pelvis. Recovery took place after many months, and nineteen months later the patient easily bore a child without artificial assistance.

HÆMATOMA VULVÆ.

LIGTERINK⁵ (Kralingen) reports two cases of this affection:

(1) A quintipara had been normally delivered by a midwife, after half an hour's labor: the placenta came spontaneously, and the uterus contracted well. An hour later the woman complained of pain in the perineum, radiating to the left leg. Three hours afterwards Ligterink found the left labium majus swollen to the size of the fist: the tumor was dark blue, the skin much stretched and almost transparent. There were no varices on the labia majora or legs. The uterus was higher than normal and inclined to the right: the bladder was empty, and in the left iliac fossa there was marked resistance and dulness. On friction of the uterus no more blood escaped than is customary four hours after labor.

Vaginal examination disclosed a tumor, which distended the left vaginal wall and reached up to the fornix. The conjecture that the bleeding had extended above the pelvic fascia was confirmed by the increase of dulness during the first hour of observation and by its persistence in spite of catharsis. The temperature was 37.8°, and the pulse 80. The treatment prescribed was absolute rest, a vaginal douche with a sublimate solution (1 to 3,000), an ice-bladder in the vagina as well as on the perineum, labium majus, and iliac fossa: also ergotin and morphia subcutaneously.

On the fifth day there appeared on the left labium near the posterior commissure a gangrenous spot,

which next day had increased to two inches in diameter: a free incision was made at this point, and the cavity tamponed with iodoform gauze. Complete recovery took place four weeks after labor.

(2) This case occurred in a non-pregnant woman, who, in falling, had struck her perineum on the point of a wooden shoe. There was no external bleeding and no wound; but two hours later the perineum began to swell and to be painful. Next day Ligterink found the right labium majus swollen to almost the size of the fist and ecchymosed. The right vaginal wall was also involved to the extent of about two inches. The same treatment was prescribed as in the first case. In due time the tumor emptied itself spontaneously: healing took place in four weeks.

[Vulvar hematomata are not of common occurrence either during or after labor, although traumatic cases may of course occur from any suitable injury. It would seem that they would be most commonly observed when the labia are the seat of varices. When developed *inter partum* they may cause decided obstruction to delivery. The treatment of *post partum* cases is well presented by Ligterink: for although in *inter partum* cases it may be necessary to lay open the tumor in order to effect delivery, it is wiser to avoid this when possible until the bleeding vessels have become effectively plugged by thrombosis. In opening the tumor, surgical asepsis, with pressure and drainage assured by the use of iodoform gauze, constitute the approved method of treatment.—REP.]

THE FUNIC SOUFFLE AND THE UTERINE BRUIT.

ETTINGER, in his inaugural dissertation,⁶ records his observations on these points in Breisky's clinic. He accurately observed twelve instances of the funic souffle, and concluded that in most cases the murmur originated in the cord itself from compression of the funic vessels, either by coiling of the cord, by knotting, or when it was unduly short. He believes that the origin of the murmur can be found only exceptionally in the fetal heart, and therefore considers the name funic souffle a proper one.

He examined for the uterine bruit in 100 consecutive cases, and found it in 88 instances: — 63 times on the left, 12 times on the right, 10 times on both sides and 3 times anywhere he pleased on the abdomen. The reason for the most frequent left-sided seat of the bruit lies in the physiological right obliquity and right lateral torsion of the uterus. In 60 cases Ettinger heard the bruit *post partum*: the bruit is heard *post partum* most frequently in multiparae.

INVERSION OF THE UTERUS, FOLLOWING TRACTION ON THE FUNIS.

CLEVELAND⁷ (New York) has reported to the New York Obstetrical Society the following case, which carries its lesson with it. Expulsion of the child in two or three pains, before the medical attendant arrived, — precipitate labor. Gentle traction on the cord, combined with gentle massage of the uterus, pending which the right cornu uteri was felt to cave in, and speedily the uterus, with placenta firmly attached, was completely inverted. The whole mass was pushed back into the vagina, while the hemorrhage was profuse and pain extreme. After some effort the uterus was finally replaced, while the patient was

² Annales de Gynécologie, 1879, p. 321.

³ Arch. de Toxicologie, April, 1880: Centralblatt f. Gyn., 1880, I.

⁵ Zürich, 1888: Centralblatt f. Gyn., 1889, 48.

⁶ American Journal of Obstetrics, January, 1890.

nearly in a state of syncope. Copious intra-uterine douches of hot water were then employed. Until the moment of using the hot water the uterus was perfectly inert and refused to contract in the least. A dose of ergot had previously been given. After hot water had been injected for a few moments, the uterus began to respond; and after two gallons had been used tonic contraction took place, the bleeding ceased, and the woman recovered. Dr. Cleveland believed that the inversion was due to his traction on the cord, although he used no greater force than he thought justifiable. In this case, however, when the uterus was inert and the placenta adherent to the fundus, he thought the slight traction employed was sufficient to cause inversion. He did not think that the pressure exerted on the fundus was sufficient to have any influence in causing the inversion in this case.

In the discussion which followed Dr. Grandin queried whether the main etiological cause of the inversion was not paralysis of the uterus following a precipitate labor, and whether in that case traction on the cord would not have caused inversion whether the placenta was attached to the fundus or to the side: and he further stated that expression of the placenta is not called for until it is loosened from its seat, which loosening only occurs when the uterus regains tone and contracts.

[Although it is perhaps unnecessary to comment on this case, the reporter cannot refrain from ranging himself with Grandin in his views on the management of the third stage of labor. There could be no better argument than the case reported against ever making traction on the cord. It can never be known that the placenta is not adherent, until after the normal contractions of the uterus, supplemented perhaps by artificial compression, having failed to extrude the afterbirth, the hand is passed into the uterus and the actual condition ascertained. There being no hemorrhage, no haste should be employed in delivering the placentas; but attention should be directed towards awakening uterine contractions, either by the gentle friction of the fundus with the hand "cupped" over it, or if necessary with ice. After contractions are excited, the uterus may expel its contents spontaneously. If it does not after half-a-dozen pains, Credé's method of expression employed *during a contraction* will surely extrude the placenta, if it is non-adherent; and if the placenta is adherent traction on the cord will most surely not deliver it. If, therefore, traction on the cord is either dangerous or ineffectual when the placenta is adherent, and unnecessary (besides being unscientific) when the placenta is detached, why should it ever be employed?]

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

GEORGE H. MONKS, M.D., SECRETARY.

REGULAR Meeting, Wednesday evening, April 2, 1890, DR. E. H. BRADFORD in the chair.

DR. G. W. ALLEN presented a communication on SOME POINTS IN THE TREATMENT OF GONORRHEA.¹

DR. A. T. CABOT said: I have been very much interested in the able presentation of this subject by Dr.

¹ See page 121 of the Journal.

Allen, and in noticing his extremely thorough treatment of his cases. It seems to me that one great advantage he has is in his thorough applications; he is sure that his medicines reach the spot; and in a great deal of the routine practice one is not. The injections formerly given to patients to be syringed into their own urethra were frequently, no doubt, useless, from not reaching the seat of the disease.

The use of nitrate of silver in most cases of chronic gonorrhœa I am interested in. It is the treatment I have been carrying out. I came to it gradually, and am so well pleased with it that I have used it in almost all of these cases, and with usually very good results. I have made applications through the endoscope, and also somewhat by injections, by using a syringe such as Uitzmann uses for the prostate. A one per cent. solution is perfectly free from any harm when injected in this way, and in a great many of the rather chronic gleet is attended with first-rate results. This method saves the urethra from the contact of the endoscope, which is more irritating than that of the urethral syringe, and is in some cases preferable on that account. In the granular condition of the mucous membrane I think the treatment through the endoscope is the true one.

DR. H. W. CUSHING: How far does tenderness to instruments correspond to diseased areas as demonstrated by the endoscope?

DR. ALLEN: I don't think you can depend on that. I think the most sensitive part of the anterior urethra, as a rule, is the floor of the fossa navicularis, and perhaps one-half inch or so back of it, but that is generally the least inflamed part, as you look through the endoscope. In a very large proportion of cases the inflammation is most intense about the peno-scrotal angle, and at the tip of the bulb it is also generally somewhat inflamed.

DR. CUSHING: That has been spoken of as rather a practical point with reference to treatment without the endoscope as designating the point at which local application should be made. If any such indication could be found, as far as routine treatment of cases goes it would save considerable time. Of course the rational method and the best method of studying the changes in the mucous membrane of the urethra is through the endoscope.

DR. ALLEN: Klotz says very decisively that tenderness is no indication of the true state of the mucous membrane.

DR. J. HOMANS, 2ND: I understood Dr. Allen to say he used a ten per cent. solution of nitrate of silver through the endoscope on a plug of cotton?

DR. ALLEN: Yes.

DR. HOMANS: When you use a solution and inject it you seldom go higher than five per cent?

DR. ALLEN: I think you would not go so high as that. When used through the endoscope the solution is applied to the very spot inflamed, and a very small quantity is used.

DR. HOMANS: My idea was that the danger of using a strong injection has been considered to be not only on account of the chance of inflaming healthy mucous membrane, but also a possibility that the treatment might produce stricture; and I merely ask for information. It would be my own feeling if I had a spot of chronically inflamed mucous membrane inside of my urethra, that I should not want a ten per cent. solution of nitrate of silver to go anywhere near it.

DR. ALLEN: You begin with a one per cent. solution and go up gradually, and as soon as you begin to see much reaction from it you stop.

DR. HOMANS: Have you had any cases under observation for over a year in which you used a ten per cent. solution?

DR. ALLEN: I have, but I have not made accurate measurements of the urethral calibre. I should not have the least fear of stricture from the solution.

DR. OTIS: What is the average amount of time required for such treatment through the endoscope?

DR. ALLEN: In an ordinary case of simple urethral inflammation, where there are no complications, no stricture formation or glandular implication, I should think, on the average, about a dozen sittings would relieve the patient of his symptoms and bring the mucous membrane pretty near to the normal condition, so that it would look very different from when you first examined it. Instead of being of a deep livid red it becomes rosy red, and then rosy pink. Klotz says the normal color is pale pink. Grünfeld says it is light rosy red.

DR. STONE said he had seen a small syringe with lanolin as a menstruum used. The exact spot for application was determined by the endoscope, and then this lanolin syringe was used as Dr. Cabot uses the Ultzmann syringe, and deposited the lanolin directly over the spot, and in that way avoided the irritation of passing the endoscope each time. The lanolin seemed to hold to the urethra and to stay much better than cocoa-butter pencils, and better than simple watery solutions.

DR. IRWIN: Does Dr. Allen consider the form of treatment he has been using for gleet preferable to the regular passage of sounds? Is it any easier for the patient? Of course I know that the use of sounds is easier for the operator. I have found steel sounds very efficacious and generally successful in the course of six weeks to two months. I think it requires a good deal of skill and considerable practice to use an endoscope, and ordinarily I should think it would be easier to use the steel sound.

DR. ALLEN: The steel sound is much easier to use, and I think it is very valuable. I have used it in connection with the endoscope. From the steel sound alone I have not had such brilliant results. I think there is a certain proportion of cases that will not get well with the steel sound. Of course there are occasional cases that will not get well with the endoscope. There are some cases of gleet that seem to be past hope.

DR. IRWIN: Have you had any experience in using the endoscope, or rather urethrascope, where a column of air is used to distend the urethra?

DR. ALLEN: I have never used it, and have never seen it used.

DR. F. S. WATSON: I wish to make a few remarks on the subject of Dr. Allen's paper, as it is one that interests me much; and I will limit them to that part of his communication which relates to chronic urethritis in the male and its treatment. I agree with the reader, that for chronic urethritis uncomplicated by stricture, the treatment by local applications through the endoscopic tubes is that which is the most certain and beneficial; and that of all the agents for this purpose nitrate of silver is that which (more especially where patches of granulation tissue occupy the urethral

surface) yields the best results; and I also concur in his opinion that in the obstinate cases the best results are gained by gradually increasing the strength of the solution up to 10 per cent. The solutions are best applied by moistening a small quantity of absorbent cotton with them, after it has been wound on a wire for the purpose of holding it firmly. I prefer the ordinary endoscopic metal tubes of Klotz, or similar ones (with lamplight or sunlight for illumination), to the electric light endoscope of Leiter-Nitze, because the former lights show the more natural colors in the urethra. I have never seen any deleterious results follow the use of nitrate of silver in the manner described that were referable to its use.

One of the most difficult matters of judgment in connection with the local treatment of chronic urethritis is that of determining the length of time and frequency of sittings to be employed in any case. I have frequently seen cases where I am sure the disease had been perpetuated by the persistence of a regular routine treatment of passing sounds twice or more weekly, and of daily astringent injections, and perhaps in addition, of endoscopic applications. That such was the case, was shown by the fact that in many instances these patients would wholly recover, on substituting a mild injection of permanganate of potash, omitting all else, or by omitting all treatment and sending them to the country or into camp.

It is well to bear this fact in mind, and to give the patient (in whose condition improvement has ceased to occur under persistent local treatment after three or four months perhaps) a chance away from his doctor, in good hygienic surroundings. With regard to the frequency of local treatment, I think the best results are seen when it is repeated twice weekly; not oftener, and frequently less often. It is of advantage to pass a full-sized sound as far as the membranous urethra immediately before making the application of the solution through the endoscope. Sometimes the sound should be lubricated with glycerine in preference to fatty substances, as the latter coat the urethra and interfere with the effects of the solution. The chief benefit derived from this procedure arises, I think, from the opening up of the folds of the urethra and exposing also the mouths of the urethral follicles to the action of the forthcoming drug.

Dr. Allen's paper covers so thoroughly the ground of the subject that I am able to do little more than to substantiate his statements, so far as my own experience in the same line may do so.

DR. ALLEN: In regard to the use of the stronger solutions through the endoscope, as Dr. Watson says, you come to it gradually. When I reported a series of cases three years ago, a three per cent. solution was the strongest I had used, but I found afterward I could gradually increase the strength.

DR. OTIS K. NEWELL: showed a series of stereopticon slides illustrating the development of

EVACUATORS FOR LITHOLAPAXY,

and then exhibited a model of what he considered to be the best form of evacuator thus far constructed. This was an instrument in which the evacuating canal is uncomplicated by trap, the evacuator itself, with its receiver, acting as one, and for which the principle of short urethral measurements makes the tubes anywhere from four inches (in children) to six or eight inches in length.

DR. A. T. CABOT said: This subject of evacuators is a large one, and one that we cannot, in the time left us, discuss at full length, and I, therefore, propose to speak only of one or two points; and I wish especially to consider the particular point in which Dr. Newell makes his evacuating tubes differ from those in use by other operators, namely, that of length. Before speaking theoretically upon the subject, I wish to state as an actual experience that since my attention has been called to the question of short tubes, I have had eight or nine cases in which the ordinary straight tube of Dr. Bigelow's was entirely swallowed in the urethra before the end of the tube reached the floor of the bladder where it ought to rest. If I had been at such a case without my tubes of full length, I should have been unable to finish the operation. It is very important in manipulations inside of the bladder, in order that you may have delicacy of perception as to what you are about, to have an instrument which is not firmly held in the soft parts outside of the bladder. If you take too short a tube, it may be impossible to tell whether the point of the tube has reached the floor of the bladder, and how hard it is pressing upon it, owing to the resistance of the soft parts which the tube pucks in front of it.

The ideal position is to have the point of the tube gently pressing the floor of the bladder, depressing it, as shown in the casts by Dr. Bigelow, in order that there may be a dependent point into which the fragments fall; and it seems important not to have a tube so short that the pressure against the parts outside of the bladder prevents properly estimating the pressure against parts inside of the bladder. If I am right in this, the ideal condition would be to have sets of tubes from which we might select a particular length for each case, a length sufficient to just reach the floor of the bladder at the time that the soft parts in front are beginning to be pressed upon. That would be a very cumbersome set of instruments to carry about to operations, and, therefore, as a matter of convenience, I think most surgeons carry one length, and select a length which is competent for all cases. The length of Dr. Bigelow's evacuating tube is materially added to by the introduction of two stop-cocks. These I think more important as adding to the comfort of the operator than of disadvantage as lengthening the operation. In the operation of litholapaxy, lasting an hour, I suppose the evacuator is not used one-quarter of an hour. The greater part of the time is occupied by the lithotrite. Perhaps by shortening the tube we could diminish it a few minutes. This would be a certain advantage, and yet in an operation of one hour the addition of five minutes is of comparatively slight importance as compared with any discomfort to the operator.

Another difficulty with the short tube is that it brings the evacuator down in very uncomfortable proximity to the patient's thighs. Any slight movement of the patient might disturb the operation; and in Dr. Newell's last evacuator, it seems to me that when the penis is pressed down and the stop-cock brought very close to the pubes, the receiver in which you want to see the fragments falling will be down deep between the legs where it would be very difficult to manipulate the instrument or to see the fragments fall.

I think Dr. Newell's point that the curved tube is often of advantage was well taken. In some cases in which the straight tube fails to bring fragments, upon

introducing the curved one, it immediately gets them. I think that it is a common plan to elevate the pelvis. It is one I have used a long time. I think Dr. Newell will remember a case on which I operated in Providence, with his assistance, in which, when the stone was not easy to seize, I elevated the pelvis with a pillow and reached the stone with perfect ease.

DR. M. H. RICHARDSON: I have not crushed many stones, but I agree with Dr. Cabot that very little time is necessary in washing out fragments. The greater part is required for crushing the stone.

It always seemed to me that Dr. Bigelow's instrument was a very perfect one. The largest stone I have crushed weighed about one-quarter of a pound. The operation of crushing and removing the fragments was less than one hour, and the greater part was necessary in crushing the fragments.

I have had no experience in introducing these short tubes, but it always seemed to me that the long straight tube or curved tube was more easily introduced when you made the urethra tense by pulling on the penis.

DR. F. S. WATSON: I see Dr. Newell's new evacuator for the first time to-night, and so do not feel competent to judge of its merits. The only objection to its form which occurred to me, is that which Dr. Cabot has already pointed out, namely, that the angle of the tube to the bulb and bottle below it is so acute that it seems as if the bulb would lie inconveniently between the patient's thighs.

Of Dr. Newell's original evacuator, and of the rise of the short tubes in connection with it, I have already spoken on former occasions, and can only repeat in brief what I said then. The advantages I have found in it are its lightness and the form of its stop-cocks. I cannot follow Dr. Newell wholly as to the desirability of his short tubes, but have adopted a length between the long ones formerly in use and his short ones, which, for cases in which there is no lengthening of the passage into the bladder from prostatic hypertrophy or other cause (which does require the full ordinary length of tube), I think is of advantage in facilitating the evacuation of fragments.

I do not think the form that Dr. Newell has given to the distal end of his tubes is a good one, as it seems to me likely to do damage to the prostatic urethra, especially in cases where a median enlargement of that organ makes it difficult to enter the bladder; and injury to that portion of the canal is one of the most dangerous accidents, so far as I have observed, that can happen in the operation of lithotomy.

With regard to the relative length of time that should be occupied by crushing and evacuating, I agree with Drs. Richardson and Cabot, and consider that the crushing is much the more difficult and delicate step of the two.

DR. NEWELL: I think the whole ground with reference to this matter is covered by the fact that a thing is sure to live on its merits.

I am surprised that Dr. Cabot thinks that the pumping is the shortest part of the operation. I should not say that at all. The greater part of the time is consumed in evacuating. In my own cases, which number two, I found that the tube was sufficiently long, and that the tactile sense is good, if you do not have too large a tube. I think it is a great mistake to use too tight instruments. It is one of Uitzmann's points that litholapaxy should be a bloodless operation.

I remember that Dr. Cabot elevated the pelvis of

the patient whom he has referred to, but I think it is not the rule to do so here. Ultzmann insists on this.

I think that the publication of Dr. Otis's evacuator put in a false light some of the points in Dr. Bigelow's evacuator, and that some claims were made which had no ground.

DR. R. W. LOVETT read a paper on

HIGH TEMPERATURE IN CHRONIC JOINT DISEASE.²

DR. RICHARDSON: In the cases of hip disease, where these high temperatures were observed in the first year or so, what symptoms of hip disease were present?

DR. LOVETT: A certain amount of limitation of motion in the affected joint, with atrophy and sometimes shortening. There was enough to establish the diagnosis, and the cases have been watched since.

DR. C. L. SCUDDER: It seems to me these observations are not only interesting, as helping to fill out the clinical picture of hip disease, but are of diagnostic value; for only recently, at Dr. Lovett's suggestion, I took the temperature of a girl with questionable lateral curvature of the spine, and the symptoms which this child presented were slight changes in the antero-posterior curve of the spine, without any marked rotation. The spine was fairly flexible, but the antero-posterior curves were altered, and it was a question whether any caries was present or not, or whether there was the beginning of a lateral curvature. The temperature was taken on several successive days in the afternoon, and each time was found to be some six or eight tenths of a degree above 99°. The probable diagnosis of spinal caries was made. These observations may prove of some value in the diagnosis between the early stage of spinal caries and that of lateral curvature.

DR. BRADFORD: Has the same elevation of temperature been observed in tubercular affections elsewhere, in the early stage—in tubercular testis, for instance?

DR. LOVETT: I cannot say.

DR. BRADFORD: It seems to me that Dr. Lovett's observations are of value in tuberculous diseases of other parts of the body.

DR. WATSON: I believe the data in tuberculosis of the genito-urinary tract are wanting.

DR. POST: Has Dr. Lovett made observations on supposed hysterical joints?

DR. LOVETT: I have had no opportunity to do so. Dr. Shaffer, in his book on "Neuromimetic Affections," speaks of elevations of temperature as not uncommon in hysterical knees.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

TWENTY-SIXTH Annual Meeting, held at Hotel Kaaterskill, Catskill Mountains, July 16 and 17, 1890.

WEDNESDAY MORNING.

The Society was called to order by the President, DR. HASKET DERRY, of Boston. The first paper was that of DR. W. F. MORRIS, of Philadelphia, reporting two cases of

BRAIN TUMOR, WITH INTERESTING EYE-SYMPOTOMS.

CASE I. Mrs. X., aged thirty-two, a strong and vigorous woman, was seen in June, 1889. During

² See page 373 of the last volume of the Journal.

the last few months there had been failing eyesight. No double vision. Movements of lid and ocular muscles good. Right pupil responded promptly to light. The left was slower in its response, and was larger than the right. The ophthalmoscope showed a low grade of hypermetropia and hypermetropic astigmatism. Discs normal. The field of vision in left eye was defective in upper outer quadrant. In the right eye the defect was in the upper and inner quadrant, but not so marked.

April 4th she had a slight convulsion. She began to have pain referred to the right side of the head and eye. May 6th, right optic disc beginning to be hazy, and slightly prominent. Left disc also swollen. Both pupils sluggish. Twitching of muscles of shoulder. Increased headache. Nausea without vomiting. Diplopia was first noted May 18th. She was seen by Drs. Wm. Osler and S. Weir Mitchell in consultation, and diagnosis of a tumor of the base, probably near the optic thalamus, was made. June 3d there was a convolution, followed by nystagmus. Death occurred July 5th. The diagnosis was confirmed by the autopsy. Microscopical examination showed the characteristic appearance of glioma.

CASE II. Mrs. Y. was seen in January, 1889. She had lost the sight of one eye, and was rapidly losing that of the other. A year previously she was seized with deafness in the right ear. Six months later she had an attack of severe pain in the right trigeminus. Later there was double vision and gradual failure of sight. The right eye was slightly prominent, the pupil semi-dilated and unresponsive to light. There was paralysis of the external rectus muscle. There was in the right eye a dense grayish haze of the retina, most marked about the nerve. The disc was slightly in advance of the retinal level. In the left eye vision was diminished, and there was a semi-transparent haze in front of the disc. There was loss of smell on the right side of the nose, and the skin and mucous membrane on this side was less sensitive than on the other. There was absolute deafness on the right side. Six days after this observation vision in the left eye was entirely lost. The patient then returned to her home. There was increased suffering from headache, and intense neuralgia in the superior and inferior dental nerves, especially on the right side. A few days before death the right eye became so prominent that the lids could not close over it. June 10th the patient became comatose and died.

The autopsy showed a large firm tumor occupying the sella turcica, extending on each side along the wings of the sphenoid especially on the right side, and also toward the base of the skull. The growth was a carcinoma, and involved the second, third, fourth, fifth, sixth, seventh and eighth nerves on the right side, and the second and third on the left side.

DR. CHARLES A. OLIVER, of Philadelphia, gave the

HISTORY OF A CASE OF INTRACRANIAL NEOPLASM, WITH LOCALIZING EYE-SYMPOTOMS; POSITION OF TUMOR VERIFIED AT AUTOPSY.

The patient, a male adult, presented general symptoms of right hemiplegia and right hemianesthesia. When first seen by the writer there was right lateral homonymous hemianopia, the left field of vision being the smaller, with well-marked Wernicke hemiopic pupillary reaction sign. In the remaining field there

were floating scotomata for green, more pronounced on the left side, with slight subnormal color perception, also more marked in the left field. In the right fundus there was a broad, superficial blotch-like hemorrhage extending over the lower outer quadrant of the disc, with enlargement and tortuosity of both the retinal veins and the arteries of the same side.

This grouping of symptoms led to a diagnosis of a gross intracranial lesion near or in the left optic thalamus. Autopsy four weeks later showed a gliosarcoma involving the external portion of the left optic thalamus as well as the corpus striatum almost as far as its anterior third. The left optic tract as far forward as the optic chiasm was markedly flattened and pressed upon.

TRANSIENT AMBLYOPIA WITH BI-TEMPORAL HEMI-ANOPSIAS IN A CASE OF MALARIAL CACHEXIA,

by DR. G. C. HARLAN, of Philadelphia.

A sailor, aged twenty-two, was admitted to the hospital September 2, 1889, with severe chills and fever. During the following month he exhibited varied nervous symptoms, headache, mania, hallucinations, etc. Quinine was given without any effect, with the exception of preventing a recurrence of the chills.

November 14th there was diminution of sight, and the patient could see only in front. Vision existed only in the nasal fields. November 18th the patient was entirely blind. The next day there was some return of vision. Microscopic examination of the eye showed pigmented corpuscles in great number. Quinine, twenty-four grains daily, caused rapid improvement. Vision rapidly returned, and on the 24th was normal. By the 30th the pigmented corpuscles had disappeared. There was no return of the symptoms.

THE EXTRACTION OF DISLOCATED LENSES FROM THE EYE, WHETHER TRANSPARENT OR CATARACTOUS,

by DR. C. S. BULL, of New York.

The author maintained that in the majority of cases it was possible to extract a lens dislocated into the vitreous by external manipulation, without the introduction of any instrument into the eye. The manipulation may be described as follows: The lids are held open by a wire speculum, and the section made upward with a narrow knife. The speculum is then removed, and the upper lid lifted away from the ball with a wire elevator. Pressure is then made against the lower part of the eyeball, the pressure being made directly backward, the lens will be seen to rise and appear at the pupil. Sometimes it comes through the pupil, but occasionally the use of a blunt hook or wire spoon becomes necessary. If continued pressure fail to push the lens through the pupil or occasions prolapse of the vitreous, some other method must be substituted. For a number of years he had not found it necessary to introduce a spoon into the vitreous chamber to remove a dislocated lens floating in the vitreous.

Dr. C. S. Bull presented

SOME FURTHER CONSIDERATIONS ON THE "SIMPLE OPERATION" FOR THE EXTRACTION OF CATARACT.

The paper was based upon some one hundred and sixty cases of cataract extraction without iridectomy,

the method of operation and the complications liable to arise were discussed in detail. The advantages claimed were: (1) If successful without complication, the natural appearance of the eye is preserved; (2) the acuteness of vision is greater than with the older operation; (3) eccentric vision is decidedly better; (4) small particles of the capsule are less likely to be incarcerated in the wound; (5) it is a shorter operation in point of time; (6) as there is no iridectomy, there is little or no hemorrhage. The disadvantages are that the technique is more difficult than that of the old operation; the corneal section must be larger; the section must be performed rapidly, and there is danger of the iris falling upon the knife; the cleansing of the pupillary space and posterior chamber is more difficult; posterior synechia and incarceration and prolapse of iris is more common. The operation is not applicable to all cases.

DR. HASKET DERBY, of Boston, reported

EIGHT CASES OF DOUBLE ZONULAR CATARACT AMONG TEN MEMBERS OF THE SAME FAMILY.

REMOVAL OF A LARGE EXOSTOSIS OF THE ORBIT WITH PRESERVATION OF THE EYE,

by DR. T. R. POOLEY, New York.

The patient was an Irish girl, twenty-three years of age, who came under observation August 21, 1888. Two years before she had noticed protrusion of the right eye ball. At the upper inner angle of the orbit a hard tumor could be felt. A diagnosis of orbital exostosis was made and confirmed by exploring incision. The patient then disappeared until February 6, 1890, when she returned with pronounced optic neuritis, V.^{—20}. Next day there was great pain in and about the orbit, with rise of temperature and mild delirium. Exophthalmus was increased, and immediate operation urged. The tumor was then removed by the use of the chisel, the mallet not being required. The bony growth measured 39 × 28 × 30 millimetres, and weighed 26 grammes. The patient was discharged at end of three weeks, and vision gradually increased to ²⁰, and all evidence of neuritis disappeared.

OPERATION FOR ECTROPION OF THE LOWER LID BY THE SLIDING FLAP METHOD,

by DR. T. R. POOLEY, New York.

The object of the communication was to show the adaptability of this operation for the relief of cicatrical contraction. The patient was a woman suffering with ectropion resulting from cicatrical contraction following the removal of epithelioma of the lower lid. The conjunctiva to the cul-de-sac was exposed. A flap was slid from the temporal region to fill the gap in the lower lid. The patient was discharged two weeks later with perfect result.

CASE OF A FOREIGN BODY REMAINING IN THE EYE ABOUT TWENTY YEARS, FOLLOWED BY ABSCESS IN THE SCLERAL WALL, OPENED AND RECOVERY,

by DR. B. L. MILLIKIN, Cleveland, O.

On March 18, 1871, E. M. O., ten years of age, was struck in the right eye with a bit of musket cap, which he supposed at the time did not enter the eye. Following the injury, the eye was greatly inflamed, confining him to his room nearly three months. The eye gave no further trouble, and vision was fair, until 1883, when he had an attack of severe inflammation in it. The eye again improved, with fair vision, and

remained well until 1887, when it again became red and painful, with failure of sight.

The patient was seen for the first time February 28, 1888. Three or four days before, another attack of inflammation had occurred. The cornea showed a linear opacity. Behind this was a slit in the iris. The ophthalmoscope showed an oblique track directly through the body of the lens. In the anterior portion of the vitreous was plainly seen a grayish-white body projecting into the vitreous, this had the appearance of an encysted body. Vision in right eye = $\frac{1}{2}$, in left eye $\frac{1}{3}$. There was tenderness on pressure over the position of the body.

September, 1889, he had another severe inflammatory attack, but was not seen until November 27th. Under active treatment the inflammation subsided.

In December, an enlargement appeared over the position of the foreign body, and rapidly increased in size. January 14th, the eye-ball was free from any general inflammation, but the projection over the foreign body had increased in size. Under cocaine, a needle was passed through the swelling and came in contact with a hard body. A triangular portion of the conjunctiva was then dissected off and an incision made into the swelling. Three or four drops of pus escaped. With a spoon a number of hard black particles were scraped out. As much as possible of the interior of the sac was removed with the spoon, forceps and scissors. The sclera was at least one centimetre thick at this point. The eye recovered without a bad symptom. The body previously seen in the vitreous chamber had disappeared. By January 22d, V. = $\frac{1}{2}$. Since the operation there has been no return of the inflammatory attacks.

FOREIGN BODY IN THE ORBIT,

by DR. W. F. NORRIS, Philadelphia.

CASE I. T. R. came under observation on account of pain in the left forehead and orbit. The eye-ball of that side was wanting. The orbit was filled with a mass sensitive to the touch, and at the bottom of the cavity was an opening discharging pus. The probe detected a hard body. He had been struck eighteen months before by an exploding railroad torpedo, shattering the left eye, which was enucleated by a surgeon, but the orbit had never healed. The patient was etherized, and a large piece of metal, which had formed the shell of the torpedo, was removed by forceps.

CASE II. P. B., forty-seven years of age, was struck in the eye by a piece of nail, which flew from a piece of wood he was sawing with a circular saw. Some days after the accident he came to the hospital. There was an opening through the lower lid and the sclerotic conjunctiva. A minute black point was seen projecting from the eye, which was found to be metallic, and on removal it proved to be a piece of nail three-quarters of an inch in length.

COMPLETE PARALYSIS OF THE LATERAL MOVEMENTS OF BOTH EYES, ABILITY TO CONVERGE REMAINING INTACT,

by DR. B. L. MILLIKEN, Cleveland, O.

M. M. L., thirty-three years of age, Irish laborer, presented himself March 21, 1890. Twelve years ago first noticed that he saw things double, but this passed off in a short time. This occurred occasionally since then. For the past few weeks had been much annoyed by the double images. The patient has been addicted

to the excessive use of alcohol, but denies syphilis. In each eye V. = $\frac{1}{2}$. When winking the left eye does not close as rapidly as the right. The eyes follow an object carried up and down in front of them, but in no position of the field can the eyes be seen to move laterally. When the eyes fix an object and this is carried towards the eyes, they are seen to converge so that the object may be carried to within seven or eight inches of the eyes. Pupillary reaction is normal. Each optic disc was small, round with narrow choroidal ring, slightly deepened pearly color and slight degree of H. There were no nervous symptoms and no history of previous illness. Ten grains of iodide of potassium three times daily was ordered, but only a few doses taken. By April 4th, the lateral movement of the right eye seemed normal, and that of the left eye was improving. The patient then passed from observation.

THE WINKING TEST,

by DR. CHARLES E. RIDER, of Rochester.

The object of the paper was to point out the relation that exists between the ability to close one eye independently of the other and the acuteness of vision. The attention of the writer was directed to this relation by the fact which he had frequently noted, that such persons as surveyors, sportsmen and others who use one eye for sighting objects, as a rule, close the poorer eye. Noting this, he was led to make a study of a series of cases numbering three hundred. The results obtained were as follows; the term isopia was suggested to indicate those having equal vision in the two eyes, and anisopia to indicate those having unequal vision:

		Male.	Female.
Cannot wink.		1	30
Isopia	{ Wink equal	30	33
	{ Wink unequal	1	27
Anisopia	{ Wink equal	17	12
	{ Better eye	4	12
	{ Poorer eye	64	66
Totals,		120	180

Of Anisopic males who winkle unequally, 99% winkle the poorer eye; and of females, 84% winkle the poorer eye.

The practical applications of this test were referred to, and its availability in certain medico-legal cases mentioned.

NEW TESTS FOR BINOCULAR VISION,

by DR. J. A. LIPPINCOTT, of Pittsburgh.

The tests suggested are the outcome of some observations and experiments, the results of which were published in *Knapp's Archives* for March, 1889, under the title of "Binocular Metamorphopsia Produced by Correcting Glasses." In practice, a convex cylindrical lens of 2 or 2.5 diopters, axis vertical, is held before one eye, and the patient is asked which side of a card ten or twelve inches square, held at the reading distance, appears the higher. The question is repeated with the axis of the cylinder horizontal. Then a concave cylinder is substituted for the convex cylinder, etc. The principal advantages which may be claimed for these tests, which are in fact stereoscopic tests without a stereoscope, are their variety and simplicity, and, moreover, the patient can be more closely watched when under observation than if his eyes are hid behind the eye-pieces of the stereoscope.

CAN HYPERMETROPIA BE HEALTHFULLY OUTGROWN?
by DR. B. ALEXANDER RANDALL.

The writer claimed that the investigations showing

the predominance of hypermetropia and the rarity of emmetropia had not been properly accepted. The assumption of the prevalence of emmetropia had little basis, and the claim that the hypermetropia which preponderates in infancy is really less in childhood, and has passed away at maturity, is in conflict with the best attested facts. Even the decrease of the grade of defect from infancy onward is slight if indeed actual. He cited the results of all the investigations, giving data as to the relation of age to refraction. These showed a very slight decrease in the grade of refraction (hypermetropia), a decrease which is really surprisingly small in view of the large amount of pathological tendency toward myopia which has been observed. The author therefore held that all tendency toward emmetropia and myopia was pathological, not physiological.

TREATMENT OF MUSCULAR ASTHENOPIA AND ITS RESULTS,

by DR. HENRY D. NOYES, of New York.

The paper was a statistical one, from which certain deductions were drawn. It was based upon a study of one hundred consecutive cases of muscular asthenopia in which prisms were employed. The cases had all been under observation sufficiently long to render the results worthy of study. Coexisting errors of refraction were found in certain cases, but the influence of such errors in the causation of the symptoms was excluded. Among the cases reported there were sixty males and forty females. The occupation of three-fourths of the cases was such as to demand persistent eye-strain. The majority of the patients were in good health, — less than forty per cent. being in a feeble condition. The symptoms noted were ocular and general. Among the former were pain, blurring and unsteadiness of print, inability to look at moving objects, inability to look fixedly at any object, difficulty in seeing the nose, protophobia, unsteadiness of the globe, spasm of the accommodation and conjunctivitis. Among the general symptoms found were headache (which often presented the singular feature of occurring on first waking and increasing during the day), vertigo, nausea, insomnia, melancholia, pain in remote parts, tenderness over the orbital nerve, and nasal catarrh.

A study of refraction showed emmetropia in forty-seven, hypermetropia in twenty-five, myopia in none, astigmatism in twenty-seven, hypermetropic astigmatism in twenty-one, myopic astigmatism in four, mixed astigmatism in two, and antimetropia in one.

The muscles affected were noted as follows: Weakness of the externi, ninety-two; weakness of the interni, four; general weakness of all the muscles, one. In five cases there was in addition a vertical error. It is to be observed that the proportion of cases of weakness of the externi is not so great as would seem from this report — the proportion is probably about 75%.

In the treatment of these cases attention was first paid to the indications presented by the condition of the general health. Many patients had been subjected to general and local treatment without relief. In some cases the use of prisms was at first tentative. In more than half the cases headache was a prominent symptom. It was in most instances relieved by the use of prisms. In some it was lessened, and in a few it was not benefited at all. In the larger number of cases prisms were worn constantly. The final results

were, complete relief in seventy-four cases, moderate relief in six, no relief in thirteen, temporary relief in six.

The report of the Committee on Blindness was then called for and read by the chairman, DR. LUCIEN HOWE, of Buffalo.

The study made by the committee showed that about 20% of the cases of blindness were due to ophthalmia neonatorum and purulent ophthalmia, and suggested certain means of prevention in the way of legal enactments.

(To be continued.)

Recent Literature.

Archivo della Scuola d'Anatomia Patologica diretto dal Prof. Giorgio Pellizzari. Volume Secondo. Firenze: Coi tipi dei Successori le Monnier. 1883.

This is a collection of articles published under the auspices of the School of Pathological Anatomy in Florence.

The first is by Dr. G. Banta, on hypertrophy of the breast. A case operated upon at the hospital furnishing the material for his studies. To his own are added an account of the published cases, and the distinction between true and false hypertrophy is insisted upon. Among the former are to be classed only those in which an increase of all the normal structures is found. In this class is placed his case, which occurred in a girl of thirteen years, whose breasts weighed, after removal, 7,200 grammes, and 3,250 grammes respectively. The illustration shows her appearance as well as the histological structure. Some importance seems to be attached to a proliferation of the epithelium lining the alveoli. But as far as can be judged from the drawing, this may be an error of observation, and the apparent thickening due to the way in which the section passed through the walls of the alveoli.

Drs. Mallochi and Pellizzari contribute a study on leprosy, illustrated by a good colored plate of the two forms, granular and bacillary, of the micro-organisms found by them in this disease.

A second article, by Dr. Banta, is devoted to splenic anemia. This he defines as "a progressive idiopathic anemia, accompanied by a pure idiopathic hypertrophy of the spleen, associated at times with that of the liver, and without leucæmia." The structural changes were found to be an increase of the stroma, chiefly confined to the follicles. The different forms of anæmia are discussed, as is their treatment, and a table is given of the cases in which resection of the spleen has been performed.

The last contribution is by Dr. Celso Pellizzari on rhinoscleroma, which has for its basis a case from the clinic in Florence. The differential diagnosis is taken up and the recorded cases given.

In his own case he had the opportunity for a careful microscopic investigation, which is illustrated by twenty figures, while a portrait of the patient gives a good idea of the external appearances of the disease.

The book is well gotten up, and, although the Italian language may be a bar for some, the figures can be easily understood, and illustrations may be rightly called the Volapuk of Science.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, AUGUST 7, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE POPULAR SCIENCE OF ECONOMIC
DIETETICS.

THERE is very little doubt but that the civilization of the future is to distinguish itself especially by a saving of the existing wastes of life. In past ages land, materials and labor have been so abundant that much of them all has been squandered; but in the older countries the crowding of population has enforced a thrift and economy to which we of the new world are as yet strangers, yet which we shall have to think more about. The farmer has been rapidly occupying the unused new lands of this continent; and the vast forests of Africa, hitherto lying waste, will doubtless, in the next century, be largely utilized. Desolated New England farms are being taken up and worked by thrifty Scandinavians. The great wastes of fuel in the existing methods of supplying heat and power will be remedied. A prominent political economist has not thought it beneath him to work out a cooking apparatus which should substitute cheap petroleum for coal, at an enormous saving of expense.

Food-wastes constitute a field in which reform is urgently needed; and it is a reform in which physicians have a peculiar interest. The slightest observation of the conditions of life among the poorer classes in our cities shows that great waste occurs in the purchase and utilization of food-products, through ignorance on the part of people who can least afford such wastes. In the houses of the well-to-do such losses are, of course, greater absolutely, if not proportionally to the whole sums expended. And how can we expect it to be otherwise? The best of our cooks are expected to study nothing but the presentation of agreeable and palatable meals; and the economics of the question, so far as intelligent knowledge is concerned, is usually outside the ken even of the mistress of the house. The latter may give general orders as to the purchases; but the good old fashion of marketing, while still retained in a few of our cities, is, for the most part, quite gone by, and too often the ordering of the food-products is patched up between the

cook and the butcher's and grocer's boys. The head of the family periodically comes down on the shopkeepers; but it is only for poor quality, over-charges or under-weights, and he never thinks of criticising the wisdom of the orders given, unless something for which he has a personal weakness has been left out.

Popular instruction of housewives, actual and prospective, not only in cooking but in the theory of food-products and in the practice of selecting such aliments as will represent the amount of the various proximate principles necessary to sustain life, while at the same time affording a variety agreeable to the palate, and involving only an expense suited to the pocket-book, will, we believe, be a necessary forerunner to that physiological millennium to which we all look forward.

The work of such men as Smith and Pavly, Pettenkofer and Voit, has laid the foundation of a science of dietetics on which other men are building a superstructure. What is needed now is a translation into a popular form of the result of such teachings. For the poor and the unlearned the instruction must be very simple and practical; and the establishment of diet-kitchens, in which it is demonstrated that nutritious and palatable products can be furnished at a low price, is a good beginning. Public bakeries, to which housekeepers can send their food to be cooked, as is done so much and so cheaply in European cities, is a fashion which might well be imitated here, though this is a matter belonging rather to the economic than the educative side of the dietetic problem.

In this connection we are glad to note that Mr. Henry Lomb, of Rochester, whose munificence has enabled the American Public Health Association to offer several prizes for essays on questions of public health, has been the means of calling forth, by a similar offer this year, a most valuable work on practical, sanitary and economic cooking, adapted to persons of moderate and small means. The author is Mrs. Mary Hinman Abel, who, we understand, has for some years been studying these problems in German laboratories, and whose work is indorsed most highly by the committee who made the award. It is stated that seventy papers were offered in competition for this prize, and that the committee were unanimous in awarding a first prize to Mrs. Abel, and in deciding that no other paper was deserving of a second prize. It is the aim of the American Public Health Association to disseminate this tract as widely as possible. It has been published in a cheap but attractive little volume, for which, we understand, the Association is prepared to arrange liberal terms.

NATIONAL MEASURES FOR THE PREVENTION OF FOOD ADULTERATION.

On another page of the JOURNAL we print a bill, which has recently been reported in Congress from the Committee on Agriculture and Forestry, for the prevention of food adulteration. In many of its provisions it resembles the bill which was introduced several years since and became the basis of similar legislation in

several States, notably in Massachusetts. Possibly the present bill is as strong a measure as could be carried through the present Congress, in which there is at least a very large minority who are strongly opposed to all food legislation whatever.

The element of weakness in the bill consists in the introduction, in the sixth section, of the words and phrases "knowingly" and "within the knowledge of the seller," which, so far as previous experience has shown, must seriously interfere with its successful operation.

Its general intent, however, is excellent, and defects can be remedied in the future.

MEDICAL NOTES.

—The death is announced of Dr. James H. Starr, who was Secretary of State under President Lamar of the Texas Republic. He was eighty-one years old.

—The catalogue of the New York Polyclinic shows an attendance, for the session of 1889-90, of 422. The following extract shows that the Faculty have resolved to exclude all but graduates of regular medical colleges from matriculating at this school: "Practitioners who are graduates of regular medical colleges, or who, having attended one or more courses of lectures at such college, have a legal permit to practise, will be admitted."

—The Park Commission of Philadelphia has decided that Edison's phonograph is a danger to public health, from the possible contagion to be transmitted by the indiscriminate use of the lobes on the rubber tubes which are affixed to the ear of the listener, and also in the liability of the instrument to cause deafness; and they have banished the instrument from the Fairmount Park.

—The trustees of the Newberry Library, Chicago, have received from the trustees of the Public Library the medical portion of the Public Library upon the conditions proposed by the public library board. These are that the collection, which was donated by the Chicago Medical Society, is to remain intact and be always open to the public. There is to be paid to the board \$1,000 to cover the cost of new medical books purchased and rebinding. These volumes will be added to the medical department of the Newberry Library and placed in charge of a special librarian.

—According to a daily contemporary there is a hospital in Brazil which bears over its gates this keen thrust at human weakness, made more emphatic by the recent abolition of titles of rank in that country: "Vanitas Humana Miserie Humanae." The late emperor, who was a philosopher, wishing to found a hospital, offered to confer a title on all who should contribute a certain sum for this purpose. The money was quickly given, and its story was engraved on the walls of the hospital in the inscription we have quoted — "Human vanity to human misery."

—The *St. James Gazette* recently contained an article recounting various instances in which women had

adopted men's clothing, and successfully concealing their sex for a greater or less length of time, had served in the British merchant service, in some privateering and piratical expeditions, and had even engaged in active fighting. Several of these persons remained undetected even after being wounded and treated in the hospitals; and, in fact, the disclosure in most instances seems to have been made voluntarily, to avoid being impressed as fighting-men, or for some such purpose. Sometimes the motive was lower, but often apparently love of adventure and excitement. One of the most remarkable cases cited is one which occurred about forty years ago, and was at that time a current topic of gossip in the army.

"An army surgeon served successively at the Cape, at Malta and at Barbadoes. This person was a small, thin, wrinkled individual, with a little voice, an effeminate aspect and strong vegetarian opinions. At the Cape he actually fought a duel with an officer who, at the mess-table, had called him a woman; yet, in spite of that, "he" was a woman, though the fact was not discovered until, having reached high rank in his profession, he died in London, enjoying the honors of surgeon-general to the army and a knighthood. Sir James Barry, as this lady was called, was well known in military circles. Many officers who can remember her are still alive."

—Mr. MacLeod, at a meeting of the Odonto-Chirurgical Society, said, according to the *Lancet*, that, having his attention drawn by a single case, he had been led to examine the teeth of various bag-pipers, and all of them represented "wearing away" of the cutting edges of the six front teeth, in a greater or lesser degree, varying with the density of the tooth structure and the time engaged in pipe playing. He found on inquiry that, on the average, it took about four years to make a well-marked impression, but that once the enamel edge was worn through the "wearing away" was more rapid. Every one was aware of the way in which the tobacco-pipe wore the teeth of the smoker, but this was not to be wondered at, the baked pipeclay being a hard and gritty substance, but that a horn mouth-piece should have such appreciable effect was, he thought, a matter of curious interest. He mentioned, however, that the mouth-pieces suffered more than the teeth, the average life of a horn mouth-piece being twelve to eighteen months, that of a bone or ivory one being about two years. The peculiarity noticed was a crescent-shaped aperture on the cutting edge of the front teeth in three localities, namely, between the central incisors and between the lateral and canine on both sides.

NEW YORK.

—A case of leprosy, of the anesthetic form, has been discovered in a boarding-house in Twenty-eighth Street, and removed to the hospital on North Brother Island. The patient is a young Central American who had recently come on to New York to attend school, and was entirely unaware of the nature of his disease, from which he has been suffering for about two years.

The case was reported to the Board of Health by the physician called in.

— The eighth special meeting of the Fifth District Branch of the New York State Medical Association was held at Kingston on the Hudson, July 22d. The principal papers read were "A Practical Study of the Region of the Spine, and Pathological Changes occasioned in it by Traumatism," by Dr. Thomas H. Manley, and "The Report of a Case of Neurotomy in Acute Purulent Pleurisy, followed by Rapid Recovery," by Dr. J. D. Sullivan. The programme of the meeting included a delightful excursion to the Hotel Kaaterskill, in the Catskill Mountains, where the members and their friends spent the night.

— The last monthly bulletin of the State Board of Health shows that during the month of June there were 8,732 deaths in the State, a number rather larger than was reported in the preceding month or in June of last year. Of these, 7,441 occurred in 136 of the cities and larger villages, having an aggregate population of about 4,165,000; which is equivalent to an annual death-rate of 18 per 1,000 inhabitants. There is a material increase in the infant mortality over the preceding month, though diphtheria caused fewer deaths. Measles and whooping-cough were of extended prevalence over the State. The proportion of deaths from zymotic diseases was smaller, however, than in June, 1889.

Miscellany.

ON THE TRANSMISSION OF TYPHOID FEVER BY THE AIR.

THE following note is translated for the *Bulletin of the United States Marine-Hospital Service* from a report by Dr. Bordas in *La Revue Médico Pharmacologique*, Constantinople, May 31, 1890.

"The writer has instituted experiments to determine the relation between the humidity of the atmosphere and the transmission of the typhic bacillus. A current of dry air, completely devoid of germs, was conducted through a vessel containing a beef-broth culture of the typhic bacillus and into a second vessel containing sterilized beef-broth. The second vessel remained sterile. The result was the same when a dry atmospheric current was passed over pumice stone saturated with a culture of the typhic bacillus. When moist air was passed through the same vessels a very different result was obtained. The sterile beef-broth culture was found, after the lapse of a quarter of an hour, to be thickly planted with the typhic bacillus.

"In nature this state of humidity is supplied by mist or fog, and statistics show an increase of typhoid fever in Paris during the months of October, November, December, and January. The most general mode of propagation of typhoid fever is by the contamination of the soil or water, but there are cases in which it is manifested by pulmonary localization. The typhic germ may penetrate into the bronchial system in spite of every means of defence possessed by the organism. Metchnikoff's studies prove that the lungs are a phagocyte battle-ground. In typhoid infection, due pri-

marily to pulmonary lesion, it would seem that the phagocytes of the lungs are ordinarily sufficient to prevent the development of the infectious germ, and that contagion, by means of the air, can take place only when the macrophagic cells cease to offer an obstacle to the invasion of the microbe."

BILL TO PREVENT FOOD ADULTERATION.

A BILL for preventing adulteration and misbranding food and drugs, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That, for the purpose of protecting the commerce in food-products and drugs between the several States and Territories of this Union and foreign countries, the Secretary of Agriculture shall organize in the Department of Agriculture a division to be known as the food division, and make necessary rules governing the same to carry out the provisions of this act, and appoint a chief thereof, at a salary of three thousand dollars per annum, whose duty it shall be to procure from time to time, under rules and regulations to be prescribed by the Secretary of Agriculture, and cause to be analyzed or examined samples of food and drugs sold or offered for sale in any State or Territory other than where manufactured. The Secretary of Agriculture is hereby authorized to employ such chemists, inspectors, clerks, laborers, and other employees as may be necessary to carry out the provisions of this act.

SECT. 2. That the introduction into any State or Territory from any other State or Territory or foreign country of any article of food or drugs which is adulterated within the meaning of this act is hereby prohibited, and any person who shall wilfully and knowingly ship or deliver for shipment from any State or Territory or foreign country to any other State or Territory, or who shall knowingly receive in any State or Territory from any other State or Territory or foreign country, or who, having so received, shall deliver, for pay or otherwise, or offer to deliver to any other person, any such article so adulterated within the meaning of this act, shall be guilty of a misdemeanor, and for such offense be fined not exceeding two hundred dollars for the first offense, and for each subsequent offense not exceeding three hundred dollars, or be imprisoned not exceeding one year, or both, in the discretion of the court.

SECT. 3. That the chief of said food division shall make, or cause to be made, under rules and regulations to be prescribed by the Secretary of Agriculture, examinations of specimens of food and drugs which may be collected from time to time under rules and regulations to be prescribed by the Secretary of Agriculture under its direction in various parts of the country, and publish in bulletins the result of such analyses. But the names of manufacturers or venders of such foods or drugs analyzed shall in no case be published in such bulletins until after conviction in the courts of violation of this act. If it shall appear from such examination that any of the provisions of this act have been violated, the Secretary of Agriculture shall at once cause a report of the fact to be made to the proper United States district attorney, with a copy of the results of the analysis duly authenticated by the analyst under oath.

SECT. 4. That it shall be the duty of every district attorney to whom the food division shall report any violation of this act to cause proceedings to be commenced and prosecuted without delay for the fines and penalties in such case provided, unless, upon inquiry and examination, he shall decide that such proceedings cannot probably be sustained, in which case he shall report the facts to the food division.

SECT. 5. That the term "drug," as used in this act, shall include all medicines for internal or external use. The term "food," as used herein, shall include all articles used for food or drink by man, whether simple, mixed, or compound.

SECT. 6. That for the purposes of this act an article shall be deemed to be adulterated—

In case of drugs:

First. If, when sold under or by a name recognized in the United States Pharmacopeia, it differs within the knowledge of the seller from the standard of strength, quality, or purity according to the tests laid down therein.

Second. If, when sold under or by a name not recognized in the United States Pharmacopeia, but which is found in some other pharmacopeia or other standard work on *materia medica*, it differs within the knowledge of the seller materially from the standard of strength, quality or purity according to the tests laid down in said work.

Third. If its strength or purity fall below the prescribed standard under which it is sold.

In the case of food or drink:

First. If any substance or substances has or have been knowingly mixed and packed with it so as to reduce or lower or injuriously affect its quality or strength, so that such product, when offered for sale, shall be calculated and shall tend to deceive the purchaser.

Second. If any inferior substance or substances has or have been knowingly substituted wholly or in part for the article, so that the product, when sold, shall be calculated and shall tend to deceive the purchaser.

Third. If any valuable constituent of the article has been knowingly wholly or in part abstracted, so that the product, when sold, shall be calculated and shall tend to deceive the purchaser.

Fourth. If it be an imitation of and knowingly sold under the specific name of another article.

Fifth. If it be knowingly mixed, colored, powdered, or stained in a manner whereby damage is concealed, so that such product, when sold, shall be calculated to deceive the purchaser.

Sixth. If it contain within the knowledge of the seller any added poisonous ingredient or any ingredient which may render such article injurious to the health of the person consuming it.

Seventh. If it consist within the knowledge of the seller of the whole or any part of a diseased, filthy, decomposed, or putrid animal or vegetable substance, or any portion of an animal unfit for food, whether manufactured or not, or if it is the product of a diseased animal, or of an animal that has died otherwise than by slaughter: *Provided*, That an article of food or drug which does not contain within the knowledge of the seller any added poisonous ingredient shall not be deemed to be adulterated—

First, in the case of mixtures or compounds which may be now or from time to time hereafter known as articles of food under their own distinctive names,

and not included in definition fourth of this section;

Second, in the case of articles labelled, branded, or tagged so as to plainly indicate that they are mixtures, compounds, combinations or blends;

Third, when any matter or ingredient has been added to the food or drug because the same is required for the production or preparation thereof as an article of commerce in a state fit for carriage or consumption, and not fraudulently to increase the bulk, weight, or measure of the food or drug, or conceal the inferior quality thereof;

Fourth, where the food or drug is unavoidably mixed with some extraneous matter in the process of collection or preparation.

SECT. 7. That every person manufacturing, offering, or exposing for sale, or delivering to a purchaser any drug or article of food included in the provisions of this act shall furnish such drugs or article of food to any person interested or demanding the same, who shall apply to him for the purpose, and shall tender him its value, of a sample sufficient for the analysis of any such article of food which is in his possession. And upon the presentation of such drug or article of food to the proper officer of the food division by a responsible person, with a request from such person for an official analysis of the same, the chief of such division shall make, or cause to be made, such analysis of the drug or article of food so presented, under rules and regulations to be prescribed by the Secretary of Agriculture.

SECT. 8. That whoever refuses to comply, upon demand, with the requirements of section eight of this act shall be guilty of a misdemeanor, and, upon conviction, shall be fined not exceeding one hundred nor less than ten dollars, or imprisoned not exceeding one hundred nor less than thirty days, or both. And any person found guilty of manufacturing, offering for sale, or selling an adulterated article of food or drug under the provisions of this act shall be adjudged to pay, in addition to the penalties heretofore provided, for all the necessary costs and expenses incurred in inspecting and analyzing such adulterated articles of which said person may have been found guilty of manufacturing, selling, or offering for sale.

SECT. 9. That in prosecutions for violations of this act proof of the act done shall be held to imply knowledge and intent on the part of the accused, unless such knowledge and intent shall be disproved on the trial.

SECT. 10. That this act shall not be construed to interfere with commerce wholly internal in any State, nor with the exercise of their police powers by the several States.

Correspondence.

"THE COUNTRY DOCTOR."

MILFORD, MASS., July 28, 1890.

MR. EDITOR: — An editorial in the *Boston Medical and Surgical Journal* of July 10, 1890, is a damper on the country doctor for not doing more to advance medicine.

It is presumable that the writer is a city born and bred doctor, who knows of the country only through his summer vacations and what he sees at the annual meetings in Boston, and judges more by the few "Rip Van Winkles" than by the majority.

The country doctor is one who advances symmetrically; he becomes rounded out in his profession from the very

necessity of his surrounding circumstances. He educates the public in a quiet way by daily contact and example. He is ingenious to adapt himself to circumstances and circumstances to his patients; and he is not confined principally, as the writer would have us believe, to prescribing for those that are simply "run down," debilitated, suffering from "functional ailments," from cold, over-work, dietary indiscretions, if my own twenty-five years' experience proves anything. How about acute and chronic lung diseases, typhoid fever, diphtheria, the exanthematosus contagious diseases, the epidemics and skin diseases, with some of which we are constantly occupied? But I see with pleasure the saving clause, which accords to him the quality of good judgment and common sense.

True, he has not the opportunity to pursue and bring to light original investigations, but he does have the clearness of sight to adopt what is good, and to be conservative in regard to theories needing demonstrative proof. He is eminently a worker, often an enthusiastic one, to the end of producing good results in treatment, and is too modest to be in haste to put before the public records of his work. His success in treatment is equal to that of his city brother, yet he rates himself below his true worth. He is often obliged to fight the battle with mortality nearly alone, because far away from affiliating counsellors, and has no near friends to share responsibility or blame. His conscience is his compass, common sense his rudder, and education the motive power that carry him through life. He does not belong to any mutual admiration society, nor does he have any journal at command through whose columns he can publish what he deems important to promulgate.

To the closing paragraph of the article in question, I will

say that I am surprised at the patronizing condescension with which the writer treats his country brother in saying, "we feel that he rather deserves praise that he is so useful a man, rather than blame that he has done so little for medical science."

Allow me to suggest that you city doctors come into the country a few years, with your notions that can be thoroughly put into practice among the wealthy city patients, and try your medical science here. You would find that you had developed seeming eccentricities, in the fact that you are too much of a specialist; and in order to succeed in a country practice you must either develop other departments, or call in other specialists, all of whom could not live.

No, my brother, you do not know nor appreciate the country doctor. He is your natural ally; he knows to whom to send such patients as need special care. Without his advice many of your patients would fall into the hands of charlatans and medical tramps.

Does he, indeed, cling to the pharmaceutical preparations of a generation or more ago? Certainly, if they are good; so do you. He is as glad to get the more elegant preparations as you are, and does so far as he can afford. But how about new remedies? The country doctor is not so much behind you as might be inferred. A few years ago one of the most eminent and progressive city doctors expressed surprise on looking into my case to find new preparations which he supposed were not used outside of the city. I do not consider myself an exception, but claim to be one among many who try, with other multitudinous duties, to keep abreast with the times.

JEROME WILMARTH, M.D.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 26, 1890, TO AUGUST 1, 1890.

With the approval of the Acting Secretary of War, leave of absence for ten days is granted Captain CURTIS E. PRICE, assistant surgeon United States Army. S. O. 175, Par. 3, A. G. O., Washington, D. C., July 29, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 2, 1890.

BLACKWOOD, N. J., assistant surgeon, ordered to duty in the Bureau of Medicine and Surgery.

WALES, P. S., medical director, ordered to duty in charge of the Museum of Hygiene.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING JULY 26, 1890.

BAILLACHE, P. H., surgeon. Granted leave of absence for seven days. July 26, 1890.

HUTTON, W. H. II., surgeon. To proceed to Chicago, Ill., on special duty. July 24, 1890.

GODFREY, JOHN, surgeon. Granted leave of absence for thirty days. July 21, 1890.

PECKHAM, C. T., past assistant surgeon. When relieved at Memphis, Tenn., to proceed to St. Louis, Mo., and assume command of the Service. July 9, 1890.

DEVAN, S. C., past assistant surgeon. Granted leave of absence for twenty-five days. July 15, 1890.

KALLOCH, P. C., past assistant surgeon. Orders of July 5th to St. Louis, Mo., revoked. July 8, 1890.

WILLIAMS, L. L., past assistant surgeon. Relieved from duty at Baltimore, Md., and to assume command of Service at Memphis, Tenn. July 8, 1890.

PERRY, T. B., assistant surgeon. To proceed to Baltimore, Md., for temporary duty. July 17, 1890.

STONER, J. B., assistant surgeon. Granted leave of absence for thirty days. July 21, 1890.

HUSSEY, S. H., assistant surgeon. To proceed to Pittsburgh, Pa., for temporary duty. July 18, 1890.

YOUNG, G. B., assistant surgeon. Granted leave of absence for fifteen days, on account of sickness. July 12, 1890.

SIMPSON, W. G., assistant surgeon. To proceed to Buffalo, N. Y., for temporary duty. July 12, 1890.

HOUGHTON, E. R., assistant surgeon. To report to the Medical Officer in Command, New York Marine-Hospital, for temporary duty. July 14, 1890.

PROMOTION.

MAGRUDER, G. M., past assistant surgeon, to rank as such from July 12, 1890.

APPOINTMENTS.

HOUGHTON, E. R., assistant surgeon, to rank as such from July 12, 1890.

BENEDICT, A. L., assistant surgeon, to rank as such from July 24, 1890.

OBITUARY. JOHN D. GRISCOM, M.D.

Dr. John D. Griscom, probably the oldest member of the College of Physicians in Philadelphia, died at his residence, at Haverford College, July 23d. The deceased was born in Philadelphia on March 23, 1809. He was educated at the University of Pennsylvania, and received his title from its medical college. He soon built up a large practice, and at one time it was claimed that he had the largest visiting practice in the country. He was said to have visited in one day ninety-five patients. Dr. Griscom was for a number of years the chairman of the Obstetrical Committee of the College of Physicians. For the past twenty-five years he had not been in active practice.

Original Articles.**SOME ASPECTS OF OUR MEDICAL SERVICE
IN THE WAR OF THE REBELLION.¹**

BY GEORGE H. LYMAN, M.D., BOSTON.

MR. PRESIDENT AND GENTLEMEN: — You have been so often instructed and entertained by exciting narrations of strategic and tactical operations, with graphic descriptions of their final culmination upon the numerous battle-fields of our armies during the War of the Rebellion, that the request for a paper upon the more prosaic medical service of that period is complied with, with great diffidence, and only upon the assumption by the chairman of your executive committee of all responsibility for any lack of interest it may have to those whose attention has never been especially called to the administrative details of this branch of the service.

If you find the personal pronoun too conspicuous, please remember that the paper claims to be only an outgrowth of a few of the *personal* reminiscences and opinions, *personal* experiences of a service extending from July, 1861, to November, 1865, over every department of the country (with one exception) in which active operations were prosecuted — illustrating as concisely as possible, by the narration of facts, occasional statistics, and more or less of free criticism, *some* of the aspects of the medical service of the war. It has been well said, that however trifling they may be in themselves, "all such souvenirs belong to history."

For any exhaustive treatment of the subject, the military historian will find abundant material elsewhere, and especially in that mine of information, the huge folios of the surgeon-general's bureau — a permanent monument to the industry and ability of the collators and the wise liberality of government expenditure for scientific purposes.

When one considers for a moment that the greatest mortality in all campaigns of any considerable duration results from disease and not from wounds, from the prolonged inaction of preparation and not the occasional shock of battle, it becomes evident at once that, without skilled sanitary supervision, the fighting efficiency of the best army must soon become demoralized and useless, and that no troops, without such oversight, can possibly be at their best, either in *moral* or *physique*. This is equally a truism when applied to the *results* of severe battles upon the continued efficiency of the survivors as an organization. The removal of the wounded from the field, the emergency dressings and operations, always accomplished in haste, under difficulties and embarrassments; the subsequent supervision of, and transportation to, general hospitals prepared in advance hundreds of miles perhaps from the theatre of war (all of which must be so arranged as not to embarrass the movements of troops); and, finally, the difficult and disheartening task of securing prompt return to duty, at the earliest possible moment that they are fit for it, of those who would willingly stay away; all fall within the direct province of the medical service, and when successfully accomplished, "properly entitle the medical department to its full participation in the glories and triumphs of the whole."² That this result was successfully accomplished by our medical officers, may, with-

¹ Abstract of a paper read before the Massachusetts Historical Society, May 13, 1880.

² Macleod on the Surgery of the Crimean War, page 10.

out presumption, be claimed for them, and at the expense of a mortuary record proportionately larger than that of any other staff corps.³

The political atmosphere of the spring of 1861 will always remain fresh in your memories. . . . The rapid assembling and departure of troops, with the exciting rumors of danger to the Capitol, kept all pulses at fever heat; and being capable of nothing else, my professional services were proffered to Governor Andrew in any way in which he could make them useful. The prompt reply was, "Go to General Schouler:⁴ tell him to give you a room and anything you require, and, so far as you can, relieve me from responsibility for the proper medical outfit of the regiments." Later, he sent Dr. Dale to my assistance, and such was the origin of the present Massachusetts State Medical Bureau. I mention this merely as a small additional record of Governor Andrew's prompt energy in his care for the soldier; and I may also add, that, whenever in doubt (not a rare occurrence, by the way), as to some large expenditure in regard to which he was consulted, the invariable reply was, "Do everything needful for the safety and comfort of the men, and I will be responsible." His thoughtful provision during the previous winter, as to army clothing, and his ready assumption of pecuniary responsibility, sent our Massachusetts troops to the front better provided than those of any other State, some of this material, indeed, being turned over by the government to other and less well-provided contingents. With the constant and almost incredible pressure upon him from every quarter, his heart never failed in eager response to any suggestion which could possibly mitigate the hardships which he foresaw to be in store for the Yankee soldier. His memorable request to the Mayor of Baltimore, that the killed of the Massachusetts Sixth should be "tenderly" sent home was but the natural expression of his loving interest in them living.

That the medical officers of Massachusetts regiments should be of the best attainable, the Governor, at an early period, provided for a careful scrutiny by an examining board, of candidates for these positions, refusing commissions to all but those who met with its approval.

In 1861, the United States had, practically, no army. A nominal regular service of less than 12,000 enlisted men (less than any one of the volunteer corps then in process of organization), scattered here and there over the country in small detachments — one of the largest of them, in Texas, obliged to give its parole and disarm — offered a barely respectable *nucleus*, while the better pay of volunteers became at once a bar to its increase by enlistment; so that, in fact, twelve months later, during the Chickahominy Campaign, the regular troops were mostly comprised in one division under General Sykes, attached to the Fifth Corps.

The medical service of the old army was, of course, correspondingly limited (115 in all).⁵ The members

³ Killed in action, 19; wounded in action (of whom 10 died), 83; killed by guerrillas, 13; killed by accidents in the line of their duty, 9; died in rebel prisons, 4; died of yellow fever, 7; died of cholera, 3; died of other diseases, most of them incident to camp life, or as the direct result of exposure in the field, 271. *Medical and Surgical History of the War*, *Part*, vol. i, p. 29; *Part*, vol. iii, p. 261.

⁴ Nor were the services of medical men strictly confined to that department of the army. A respectable quota of the profession in Massachusetts entered the service as privates or as line officers, the latter either by original commission or after resignation from the medical corps. Adams, Draper, Sargent, Stedman, Wild, were examples from Boston.

⁵ Adjutant-general.

⁶ *Medical and Surgical History of the Rebellion*, vol. iii, p. 299.

of this small staff, with the exception of those who had served in the Mexican Campaign, with its small army, had necessarily little or no experience in active field operations on a large scale. Subsequent to that period, they had been scattered over widely separated posts garrisoned by small detachments, and far from those opportunities for constant mental attrition with professional *confrères*, so useful, and indeed necessary, as a stimulus.

They had had no such ample facilities for practical experience and mental culture as are afforded to their *confrères* in the services of Europe, with their large garrisoned cities near universities, medical schools and hospitals, resources freely open to them, and of which they not only can, but are *expected* to avail themselves. I make no invidious comparisons or ungenerous criticism—I mention only facts as they existed and for which they were not responsible—which, indeed, many, especially of the younger men among them fresh from civil life and its opportunities, who had lost none of their enthusiasm for professional progress, repeatedly deplored. Some, in fact, left the service after the termination of the war, and now rank among the most prominent and able medical men of the country.

It should also be said, that at the opening of the war, the organization and rapid development of the service gave to these older officers a prominence which was justly their due. Their familiarity with administrative duty, indeed, made it indispensable, not only in the purveying department, but in organizing centres away from the theatre of active operations. The surgeon-general himself, however, was soon found to be too superannuated for his position, and was, without hesitation, superseded by a comparatively young man, thus breaking, once for all, the iron-bound rule of seniority; but the emergencies of the time overrode all precedent, and the same course was soon adopted throughout the service as occasion required. Of course, discontent, jealousy, and sometimes decided friction were manifested whenever occasion offered, and, perhaps naturally enough, they were especially intensified towards those appointed from civil life.

Medical and surgical science had made vast strides in the preceding quarter of a century, and a large proportion of the volunteer medical staff were, to say the least, quite their equals in theoretical and practical acquirements. To men with the intellectual gifts of Bell, Hamilton, Bryant, and hosts of others, this friction, amounting as it often did to insolence, was well-nigh unendurable, taxing their patriotism, patience and good-nature to the utmost. For the younger men—the majority of the regular corps—too much cannot be said in praise. They had entered the service under different conditions as to requirements, the stimulus of knowledge was still alive, and when not hampered by the routine of bureau work, they displayed on all occasions professional ability and energy of which any army might well be proud. Men like Coolidge, Murray, Letterman, Bartholow, Woodward, Gooley, Webster, Woodhull, Otis, Billings, and others of that stamp, need only be mentioned in proof.

Under these circumstances, then, the great volunteer host so suddenly called to arms had to be supplied from civilian ranks, not only with its general and line officers, but with its medical staff; and these may proudly claim that no nation in the world has shown more brilliant results of medical, surgical and sanitary

skill than were finally accomplished in this prolonged and bloody contest. From the beginning, men of the highest reputation in the profession promptly offered their aid; and although as the war progressed, and the demand so largely increased, recruits for the medical service were more difficult to obtain, the available supply of this grade of men becoming exhausted, and recourse being necessarily had to recent graduates, or even under-graduates, it was but a repetition of the experience of all great armies. In the Franco-Prussian War, the German army, notwithstanding its thorough organization and years of preparation, required over two thousand civilians in addition to its regular medical staff, during the short period of seven months of active operations in that campaign.⁴ Under the First Empire, it is said that at least half the medical men in the military service were under-graduates, having neither the capacity nor legal right to prescribe.⁵

The study of medicine, surgery and sanitary science, in their especial application to military operations, had, of course, been much limited in this country—no Larrey, Percy, Guthrie, Langenbeck, nor Baudens to give an initiative in that direction. Yet here, as elsewhere, our countrymen were equal to the emergency; readily adapted themselves to the new conditions by study and practice; learned by heart that army gospel, the Regulations; and, it may be added, soon learned to obey or disregard the same as circumstances required—for they were on too narrow a scale for the time. It was not always possible to "get a quart into a pint pot."

As showing that doctors were not a mere ornamental appendage, a few words of statistics will not be inappropriate: The total cases of wounds and disease with which they had to deal, from May, 1861, to June, 1865, reached the enormous sum of 5,825,480 whites and 629,354 blacks, of which total 210,000 were fatal. This does not include sickness and death among prisoners of war. The number killed in battle or dying of their wounds (exclusive of accidental injuries) was 93,960 out of a total wounded of 236,000.⁶ The sickness from all causes was greatest during the first months of the war, but from special causes such as malaria, diarrhoea, dysentery, etc., aggravated by paludal influences, the greater mortality occurred naturally at a later period. It is peculiarly noteworthy, as against all anticipations, that the colored troops suffered more frequently and fatally than the whites from malaria, "succumbing quickly under morbiotic influences."⁷

Congress having, early in June, 1861, made provision for twenty brigade surgeons of volunteers to be commissioned by the president, after examination by an army board, Drs. Bell, Bryant and myself appeared at its first meeting, June 28th.

This corps of brigade surgeons was originally added to the army, under the supposition that they would have supervisory authority over the regimental surgeons, but being assimilated with the regular medical staff, they really ranked by date of commission, and could only exercise such authority over regimental surgeons as they derived from their assignment to duty as medical directors of brigades. At a later period,

and Surg., vol. III, pp. 27, 962.

⁷ Loc. cit., pp. 12, 64.

as will be seen, this difficulty was met by another act of Congress appointing a corps of eight medical inspectors (afterwards increased to sixteen) with the rank of lieutenant-colonel. . . .

In September, 1861, I was assigned as medical director to the division originally organized by General Sherman, then in camp opposite Georgetown under command of General Fitz John Porter.

A line of earthworks, extending from Chain Bridge above to Alexandria, some ten or twelve miles down the Potomac, was in process of construction, behind which the organization of the Army of the Potomac was constantly progressing as troops arrived. The air was full of rumors and false alarms sufficiently exciting to the inexperienced, — a category, by the way, comprising, with few exceptions all, from generals to privates.¹⁰

You all remember the unavailing cry of "On to Richmond," and the disgust with which the army went into winter quarters to consume their supplies and growl at the discomforts of inaction. The *ennui* was perhaps less to the medical staff, inasmuch as the daily routine of duty over the extended lines in the sanitary supervision of camps and hospitals, the elimination through examining boards of some worthless professional material, devising improvements in heating and cooking, with the direct attendance upon the sick, who, unused to camp life, required constant care and encouragement, left us little time for growling. This inaction in camp is always to be deplored; not only does its influence upon the sick list become at once apparent, but the experience of all armies proves that it becomes the foundation for a dangerous development of disease, when, at some later period, it becomes necessary to make heavy drafts upon the energy and vigor of the soldier. Indeed, in our own case, before the winter was over, direct manifestations of this truth became apparent in a low form of remittent fever, subsequently known throughout the army as typhoid malarial. . . .

The month of delay in siege operations before Yorktown, though useful to the medical department in giving an opportunity for revision of supplies and disposing of the sick and disabled, was of no service to the troops in a sanitary point of view, — the bayous and low grounds from the York and James rivers on our flanks favoring the development of malaria; though entire freedom from this was not to be expected on the peninsula.

An illustration of the animus of some of the old surgeons toward those of the volunteer staff at the beginning of the war occurred while here. The brigade surgeon placed in charge of the division hospital reported that the chief medical director had superseded him, by an order placing a civilian, one of a temporary deputation from New England, in charge. He was promptly directed to ignore any such order,

¹⁰ Orders from Washington were of almost daily frequency, enjoining upon medical officers the need of complete preparation for impending active service. Among others was a peremptory one as to improper use of ambulances, especially by officers for excursions to Washington and neighboring camps. Among other duties in Boston, I have heard of for a number of light Convoys wagons and hospital transport, but like others of the abolition supplies from Massachusetts, these vehicles were devoted to other uses at various headquarters. The abuse became so great at last, that McClellan ordered medical directors to report every case of their illegitimate use. What was to be done? Report to the War Department? Hooper riding to and fro, comfortingly, in one of them? What was to be done? Report the chairman of the military committee and a member of the House? After some chafing by the mess at my dilemma, it was done to the amusement of the others, and for a short time, and a short time only, with good effect.

unless received in the regular course through division headquarters.

Reporting the facts to General Porter, he at once interviewed the medical director, and so emphatically as to prevent any future repetition of such procedures.

It was a common custom during the war for such deputations of medical men to come to the front to offer their services for the sick and wounded. Such visits were a novel experience, a chance to observe all that was going on, and to do any operating which might fall in their way. As a rule, subject to many brilliant exceptions, the occasions were rare indeed in which they seemed over-solicitous to relieve one of the nursing and drudgery, for which there was such abundant opportunity, as our medical officers had been all winter under canvas, familiarizing themselves with their duties in anticipation of the more active professional work in the field, it seemed to them very unjust that they should be superseded by "curiosity hunters," who could at pleasure be welcomed to their homes with a flourish of trumpets for their self-sacrificing patriotism. This particular case was more aggravating from the unjustifiable action of the chief medical director, who, as an old army officer, knew better, and from the want of courtesy shown by old acquaintances, who, knowing my position perfectly well, had neither the courtesy nor good feelings to make their presence known. So far as I know, all such deputations invariably received a cordial welcome, whatever their motives, but it was not unreasonably required that they should come "by the front door." For ordinary surgical service, no help was needed; for emergencies, no one could be otherwise than thankful for outside aid, when offered in a proper spirit, as was cheerfully recognized a little later, when these same gentlemen rendered most valuable service at Williamsburg. . . .

May 22d, the Chickahominy was reached at Cold Harbor, destined later to be the theatre of two desperate battles, namely, Gaines' Mill (so called), on June 27th, between the Fifth Corps, and the Confederates under Stonewall Jackson, Longstreet and the Hills, and two years later, when Grant made his last effort to reach Richmond north of the James, and known as the battle of Cold Harbor. The Fifth Corps went into camp a short distance above at New Bridge, upon the extreme right of the army.

Any detention in this locality, it was again prophesied, would cause a rapid development of malarial disease. Though this undoubtedly increased during the five weeks of delay here, it is more than probable that the locality was not the only cause, for, if the experience of other armies may be trusted, the long inaction of the previous winter, and the slow progress up the Peninsula, followed by the exhausting work on corduroys, and the bridges over the Chickahominy, were important factors in this development.

Diarrhea prevailed very generally among officers and men. It was perfectly rebellious to treatment, and later, in its chronic form (as I have good reason to remember), continued for years; but true dysentery, that scourge of armies so situated, never obtained extensive foothold — thanks to careful camp police, the abundance of desiccated vegetables, and the general good quality of the rations.

The first cases of scurvy developed here, in the regular brigade of our corps. This unwelcome information, forwarded to general headquarters, was received with incredulity, but confirmatory cases soon mani-

fested themselves in the vicinity. Supplies of lemon juice and fresh vegetables coming in, the disease was soon checked. Desiccated vegetables were made *compulsory* so far as possible, but the troops were always averse to them, avoiding their use where they could. . . .

Hanover Court House was our first experience, and, though not a large affair, was enough for initiation. The wounded were collected, dressings and operations performed until dark, when, the fight being hardly over, it was necessary to stop for want of candles, stimulants, dressings and portable food, of which there was an abundant supply on the train at the rear, but inaccessible when wanted. Bearers and stretchers were obtained with difficulty.

Although General McClellan, who had come up at night, was disposed to be very complimentary, the day's experience was by no means satisfactory to me, in view of the severer engagements in anticipation.

Under the old régime these difficulties were more or less unavoidable, and indeed became so manifest later on, that, as will be seen, an attempt was inaugurated, July 4th, at Harrison's Landing, by the new medical director, Dr. Letterman, for the re-organization of the ambulance service. Some of the reasons for this may be properly alluded to. It is manifest that an active opening at noon, or even earlier, and lasting until dark, gives little chance for the prompt treatment of the wounded, without a properly organized corps of bearers keeping pace with the movements of the line—men of sufficient experience to do their work without interference with those engaged—picked men, enlisted for that duty, and wearing a distinctive uniform. They should be drilled in the peculiar requirements of the service, such as the proper handling of the wounded, the use of restoratives, and the temporary arrest of hemorrhage, their extrication from the *melee*, and rapid transfer to the nearest relief station. Such a command, under its own non-commissioned officers, should be directly responsible to the medical staff. By the practice then relied on, musicians, hospital attendants, and individuals unfit for other duty, were the sole dependence, and it is useless to say, the graver the emergency, the less that reliance became.

Special details for such emergencies, even if granted, are a snare and delusion, for no commanding officer is likely to detail his best men, until, at any rate, the fight is over very late in the day, by which time a blind man would be as good as any.¹¹

As early as April, 1862, the new surgeon-general, Hammond, writes¹² to the Secretary of War of the "urgent need" of re-organization. "In no battle," he says, "have the wounded been properly looked after; men leave the ranks under pretence of carrying their comrades from the field, and seldom return." He claims that the adoption of this plan (referring to one submitted) would obviate the necessity of taking men from the line as nurses, cooks and attendants, and thus "return 16,000 men to duty in the ranks." His proposition being refused as inexpedient and unnecessary, he writes again in September, calling "attention to the frightful state of disorder existing in arrange-

¹¹ Says Macleod (*Surgery of the Crimean War*, page 8), as a result of his Crimean experience: "Steady soldiers of character, or men especially recruited, form a distinct corps, retaining the military spirit and constituting a force from which they can be sent and well fed, having fixed duties and regular training, and liable to military service, entirely under command of the medical officers, and yet subject to military discipline—such is a rough outline of the corps which would render the best service in the hospitals of an army in the field."

¹² Medical and Surgical History of the War, page 204, et seq.

ments for removing wounded from the field of battle"—to which Halleck replies in his contemptuous, bureaucratic style, that "the enemy provide for *their* wounded, with not one-half of our ambulances and facilities," adding—what was well enough known before—that it is the duty of all officers to furnish fatigue parties on requisition—as if it were perfectly feasible to get in a requisition or tell off the men during an engagement.

Although, as I have said, Dr. Letterman made the first real step in advance, it was not brought to the best results attained during the war, until 1864, when the struggle was nearing its end.

It would be well if our war department could realize, in advance, that in a war of any magnitude—should such again occur—the true ideal will never be reached, with anything short of a specially enlisted corps, under the direct orders of the medical department, and regardless of increased expense, which, by the way, would be comparatively insignificant, regard being had to the number already allowed—the loss of fighting material leaving the ranks to aid their comrades—and, above all, the saving of lives now unnecessarily wasted by hours, and even days, of exposure, unknown and uncared for.

Another embarrassment existed in the absence of co-operation—often direct antagonism—between the medical and quartermasters' departments, unavoidable under the then existing organization. Hospital wagons and ambulances of the train should be in special charge of an assistant-quartermaster, taking precedence of all but the ordnance when an action is impending, keeping in touch with, and directly responsible to the chief medical officers, where they would be readily found to deliver supplies as required, and, when vacated, serving, if needed, on occasion, as temporary ambulances. Hospital transports and boats, fitted at great expense, were not rarely diverted to other uses by the quartermaster's department, against all remonstrances, until finally, near the end of the war, they were placed where they should have been long before, under the exclusive control of the medical department; by order of the Secretary of War (February 8, 1865).

Returning to camp at New Bridge, I resolved to attempt an improvement in one direction at least, and encouraged by General Porter, obtained a large covered six mule wagon, filled with ample extra supplies, with a small one horse cart for ready distribution of the same, all to be kept strictly intact for emergencies only. They were stationed behind my tent. This Yankee notion occasioned gibes and jokes from high and low. Soon the quartermaster proposed sending my mules back to White House, to draw their own forage. I protested against this entering wedge. The general thought me unreasonable; but after a lively scrimmage with the quartermaster, I was sustained, and that wagon went through the subsequent Seven Days' Retreat on time, dispensing its blessings where needed, not only in the Fifth but adjoining Third Corps. . . .

Having been notified some days before to get rid quickly and quietly of all the sick and the hospital impediments not actually needed, they were sent over the Chickahominy; and in the afternoon of June 26th, the operations of the memorable Seven Days' Retreat to the James River were initiated by the crossing of Lee's left at Meadow Bridge, and an assault

upon our field-works at Beaver Dam and Mechanicsville. This onslaught was repulsed with great loss to them; but the simultaneous approach of Jackson from Hanover, upon our right rear, rendered necessary the concentration of the corps in better position a little farther down the stream. . . .

In reviewing this retreat, it is not easy to see how more could have been done by the medical department. All plans were necessarily subordinated to the operations and movements of the troops. There were seven days of continuous fighting and marching, over roads encumbered with trains, artillery, and three thousand cattle; while at every lateral *embouchure*, the enemy were ready to interrupt the march. A large field hospital at Savage's Station absorbed great numbers of wounded, others being brought along in ambulances, or struggling along, when able, on foot. Commissary supplies and transportation, though much had been destroyed, were all (and more) that could be well managed or made useful. As it resulted, many wounded were, of course, left in the hands of the Confederates.

It had now been generally recognized that methods of detail in the medical service were in urgent need of revision; and the chief medical director (now Dr. Letterman, who had replaced Tripler, July 3d) organized a board to devise new methods for the ambulance service. Although a member of this board, I was able to attend only the first meeting (and at that required assistance to dismount), having been a victim to malarial disorder since leaving Howard's Bridge, April 5th, weeks before.

A few days later was ordered to report in Washington for assignment to duty as one of the new corps of medical inspectors.

Before leaving the Army of the Potomac, however, I had occasion to witness another instance of President Lincoln's simplicity and indifference to all ceremonial. He had come down on his celebrated visit to see for himself what McClellan was about, and was given a night review, the field being illuminated by enormous brush fires. The review over, he became, of course, the centre of attraction. After a pleasant talk with this group, and bidding General McClellan good-night, he remarked that it was "about time to be getting home," evidently intending to make his way to the boat alone, regardless of escort, but was soon made aware that the commander-in-chief of the American armies could not be so unceremoniously treated, and though he thought it quite useless, was escorted to the wharf by the large *cortege* of general officers.

(To be continued.)

When removal of the uterine appendages was proposed, but long before the just and true principles on which it is now based could be formulated, everybody rushed into the trial of it, and the result was a disastrous epidemic, the chief burden and discredit of which fell upon me. I was more horrified than I can tell; and much of my time was taken up in disclaiming the doubtful honor of what was called "Tait's operation," in the performance of which every principle advocated by Tait was neglected, or deliberately outraged. If the men who engaged in this work had waited for a reasonable trial, a fair discussion, and a just verdict, much discredit for our art would have been spared us.—*Lawson Tait's Address in Surgery at the British Medical Association.*

SOME OF THE RELATIONS OF CLIMATE TO HEALTH AND DISEASE.¹

BY W. EVERETT SMITH, M.D., BOSTON,
Committee on the Distribution of Diseases.

LIVING as we do in a constant atmospheric bath, it behoves us to know something very definite if we can of its relations to the physical conditions of our bodies. To consider the relations of this bath to our respiratory organs alone is to discuss a portion only of our subject. Yet I know of no attempt to discuss the matter adequately, although many partial discussions have laid claim to be complete and exhaustive treatments of the subject. Nor is it possible in the brief time here allowed to do more than to clear away some of the deep fogs and to outline the barest statement of such beliefs as our daily observation proves are founded upon facts.

Diseases have been too often regarded more as entities with a single exciting cause than as progressive tissue changes with many exciting causes, that are revealed to us moreover not by *a priori* reasoning but by symptoms. The influence of the weather upon disease has been exaggerated; we have not yet established logical and scientific indications for preferring one climate to another,² and the result has been that our experimental attempts to find an ideal climate for a given disease have been at times disastrous rather than helpful to the patient.

Absolute Humidity.—Let us begin with the consideration of humidity. Nearly every argument upon this subject is based either upon the definite statement or else the assumption that the absolute humidity of the air (the weight, in grains, of aqueous vapor per cubic foot of air) is dependent upon temperature. It is nothing of the kind.³ At all temperatures, even the lowest, there is a process of evaporation going on, modified by many varying conditions, among which may be mentioned the direction, temperature, velocity and character of the winds, whether they be wet or dry. Air is cooled and rendered less able to hold aqueous vapor until at last a temperature, the dew point, is reached, at which vapor begins to be condensed.

Practically this dew point is determined by the readings of a dry and a wet bulb thermometer, since the difference between them has been empirically obtained and mathematically tabulated to bear a certain ratio to the complement of the dew point, that is, to the difference between the temperature of the air and of the dew point. In order now to estimate the weight of aqueous vapor actually present in the air, it is necessary to have determined the elastic pressure or tension of vapor (that is, the amount of barometric pressure due to aqueous vapor), not at the temper-

¹ Read before the Massachusetts Medical Society, June 11, 1860. In 1852 Dr. Smith read a paper before the Society, entitled "A Study of Pithisis and Pneumonia in Massachusetts." He was thereupon appointed a committee of one to co-operate with Professor Shaler and General Greeley in studying the distribution of diseases, and the solution of more intricate problems, presented themselves than he suspected when he accepted the appointment. He has been pursuing the work with much diligence and zeal for the past two years, and the present paper was intended as a sort of preliminary report. He died after a brief illness while the proof-sheets of this article were awaiting his final revision.

² Although we know, for example, that a wet soil favors disease, there are reasons for believing that this is not in itself a law governing disease, but only a particular instance of distribution under some circumstances.

³ It is true that with a high temperature there is, as an abstract law of physics, a possibility of more aqueous vapor being present than with a low temperature. We are not, however, discussing possibilities, but actualities of our daily surroundings.

ture of the air, but at the temperature of the dew point. The weight of aqueous vapor can then be calculated.

It is evident first, that the dew point does not depend upon the temperature of the air; secondly, that the temperature of the air has nothing to do with absolute humidity, except to fix the highest possible limit to its amount; thirdly, that it is the vapor tension of the dew point which fixes the actual amount of aqueous vapor present at a given air temperature.

To these rules one exception should be made. When vapor tension is at its maximum, that is, when the air is said to be "saturated" with vapor, the complement of the dew point is zero, that is, no evaporation is going on, and there is no essential difference between the readings of the two thermometers. At such infrequent times only does the absolute humidity depend upon and vary with the temperature of the air.⁴

Now can we say that there is such a general correspondence between the curves for air temperature and for absolute humidity that for all practical purposes we can assume an inter-dependence. The curves upon study are found not to correspond closely with each other; indeed, we know that the same degree of temperature will by no means always cause the same degree of absolute humidity either in the same or in different localities. For example, Boston, Denver, Santa Fé, Boise City and Winnemucca, Nevada, have all nearly the same degree and curve for temperature; yet Boston has a much higher degree of absolute humidity than has any of the others, while Denver, Santa Fé and Boise City have more than Winnemucca. In Denver and Santa Fé, too, may be seen how little of mere similarity exists between the curves for temperature and the amount of aqueous vapor.

Relative Humidity.—Turning now to the consideration of relative humidity, we find it to be usually defined as the ratio or percentage of the vapor actually present at any time in a given volume of air to that required for the full saturation of the same volume.

Such a definition plunges us deep in an inextricable confusion of ideas by employing terms which have survived long after the theories have disappeared under which they were developed. Moisture, dryness, humidity, vapor and saturation are rarely used with precision and consistency in even scientific discussions. What can be more perplexing, for example, than to find that after a writer has discarded as worthless the data of relative humidity, he continues to refer to "sensations of dampness," to illustrate the fact that although over a wet soil we find a low temperature and a small absolute humidity (a dry air), we frequently find also an atmosphere "saturated" with moisture. We all know that a wet soil is a cold soil, has a high relative humidity and often a misty atmosphere; can the locality be considered both wet and dry at the same time?

Somewhat akin to this is the common and unfortunate confusion with each other of clouds, mists, fogs, dew and true vapor, the use of the terms humidity and moisture to include both true and partially condensed vapor, and finally the use of the term vapor when we do not mean true vapor, but only a liquid water in a

state of extremely fine subdivision. This is a relic of a seventeenth-century idea that the "particles" of water vapor or the minute cloud particles with which true vapor is often confounded are of vesicular form, that they are minute bubbles instead of drops, and that they can therefore float freely in the air. Although the air may be full of moisture in the shape of globules of water for hours without a large amount of true aqueous vapor being present, true vapor is not sustained in the air like water in a sponge, nor does it float like particles of dust. It is one of the actual gases of the air, sustains itself like other gases, and is governed by the laws of gases, so that, using air in its general sense, we should say that air contains watery vapor just as it contains oxygen.

A similar confusion of ideas is embodied in the use of the term "saturation" of air, as though air dissolves and holds water in the form of vapor, much as water dissolves salt. The air does nothing of the kind, for at a given temperature the same quantity of vapor that can exist mixed with air may pass into a vacuum and remain there without the presence or aid of air. Relative humidity, then, has no relation to air, but according to a law of gases is, strictly speaking, a relation between vapor and the space it occupies.

In other words, relative humidity is a ratio of elastic pressures, the elastic pressure of the dew point and the elastic pressure of the air temperature.⁵ As the dew point approaches or recedes from the air temperature, so will the relative humidity or the evaporating power of the atmosphere vary. Instead of saying that the vapor now present is a certain per cent. of "saturation," it would be more precise and far less confusing to say that the tension of the vapor now present is a certain per cent. of the highest possible vapor tension at the given air temperature.

Objections to Relative Humidity.—It is evident at this point that the reason for accepting *absolute* and rejecting *relative* humidity, because "our knowledge of the humidity of the atmosphere is not gained by the simple observation of an instrument as is our knowledge of the temperature, but through laborious computations by means of tables and employing the results of observations of two instruments—the wet bulb and dry bulb thermometers—so that there are more chances for errors in observation and computation,"⁶ is not a valid one. Both sets of data are derived from the same instruments and the same observations; the labor of computation and the chances for errors are no greater in the one case than in the other, while in neither case are they especially laborious.

The objection that has been made to the use of *relative* humidity, on the ground that it "is not a per cent. of some fixed quantity, but is a per cent. of a quantity which varies with every degree of temperature,"⁷ is more plausible and confusing. Strictly speaking, however, the quantity represented by "100 per cent. of saturation" is a very fixed one, being the quantity of aqueous vapor which will give the highest possible vapor tension at the given air temperature; and this

⁴ Yet this exceptional atmospheric condition is substituted in arguments for ordinary, every-day conditions, and is the base upon which the whole superstructure of the "dry-air" theory of disease is reared. See Annual Report of Michigan State Board of Health, 1881, page 427.

⁵ The Causation of Pneumonia, by Henry B. Baker, M.D., in Annual Report of Michigan State Board of Health, 1886, page 285. We might add here that the author intends to reject all data of humidity whatsoever, and estimate the absolute humidity by the simple observation of the thermometer.

⁶ Report of Michigan State Board of Health, 1881, page 427.

⁷ Since vapor tension and absolute humidity are correlated terms, we can express the relative humidity as a ratio of the weights of aqueous vapor, that is, by a ratio of the absolute humidities corresponding to the given vapor tensions or elastic pressures.

vapor pressure is definitely fixed for every degree of temperature." If, on the other hand, it is meant that the vapor tension represented by 100 per cent. varies according as the air temperature varies, it does not, because of this fact, vary with any greater irregularity than does the absolute humidity which depends upon a varying dew point. Nor does it represent anything that is "unreal," fictitious, problematical or hypothetical about the atmosphere. It represents actual conditions of our surroundings, just as true and just as important to us as absolute humidity; but not the same conditions.

Influence of Relative Humidity upon Health.—If water evaporates into dry air, the elastic force of the vapor tension is increased and the mixed vapor and dry air, if free to expand, as is ordinarily the case in the atmosphere, will occupy a larger space than did the dry air. When, then, the relative humidity is high we inhale at each inspiration slightly less of oxygen than when the relative humidity is lower.¹ The difference is slight, yet we all have noted the influence of muggy weather, not only upon our feelings and moods, but upon our mental and bodily activity, and it does not seem improbable that some of this languor may be due to a slight diminution of the oxygen we breathe.¹⁰

There are, however, more important reasons why the degree of relative humidity is of value to the physician. Since relative humidity is the measure of the evaporating power of the air, it is evident that the expired air will be less rapidly evaporated in the buccal passages when the relative humidity is high than when it is low. Besides CO₂, this vitiated air contains various organic impurities — albuminoid ammonia — which rapidly putrefy, and are in part the cause of the odor of the breath. It is probable that many of them are of a poisonous nature, since an atmosphere which contains simply one per cent. of CO₂ has very little effect upon the animal economy, while an atmosphere into which one per cent. of CO₂ has been passed by breathing is highly injurious.¹¹

Another potent factor in health is perspiration, not merely the sensible but the insensible, which passes off

¹ Since the very meaning of the idea of "saturation" must be a coincidence of dew point with air temperature, we determine our 100 per cent. by regarding the given air temperature as the dew point.

² At 80° F., for example, when the relative humidity is 90 per cent., the volume of mixed air is one-thirty-third greater than that of dry air, but when the relative humidity is 100 per cent., the volume is only one-fiftieth greater. Patients with asthma, advanced lung trouble or heart disease, quickly detect such differences by the increased difficulty and rapidity of breathing when the relative humidity is high. This is an effect not made clear by another way. Air containing vapor is specifically lighter than air when without vapor. The weight of a cubic foot of dry air at 60° F. is 0.06.28 grains, and that of a cubic foot of vapor at 60° F. is 5.77 grains. These conjoined weights would be 542.05 grains, but owing to the enlargement of the air the actual weight is 532.84 grains.

³ In those localities where the air is very rare, this diminution and diminution of oxygen is of course observed in much greater degree, but the involuntary increase in the frequency and deepness of respiration fully compensates for it, since it is not until the oxygen sinks to about 14 per cent. of the air that its full supply can be obtained. The body's own oxygen is very slow indeed, which is the most physiological, complete and satisfactory one (see my paper on The Cause of Sleep, in Boston Medical and Surgical Journal, May 6, 1880), depends upon the diminution of oxygen in the tissues of the body. Hence sleep is a cessation of bodily and mental effort, in order that the body may not be so rapidly oxidized, but may be stored up in the system. Aoxenine will then take place when sufficient oxygen has accumulated for the maintenance of bodily activity.

⁴ The nitrogenous matter accumulated in air may be in the form of dead or living material of various kinds. It is probably in combination with water, since the most hydroscopic substances absorb the most of it. It may be a reason, additional to the possibilities to be given later in this paper, for the unhealthiness of low wet soils with great moisture in the air. See also Report on the Meteorological Conditions and their Relations to the Epidemic Influenza, by N. S. Davis, M.D., LL.D., Journal of the American Medical Association, June 7, 1890, page 517.

at once as watery vapor, containing, like the breath, volatile effete material. In proportion as the evaporation of this perspiration is impeded, these products must be excreted by a vicarious activity of other organs which may resent the imposition, or else will be reabsorbed within the system and cause, not only disagreeable odors, but morbid inactivity of the functions of the sweat glands with a slight pyrexia and mild degree of systemic poisoning. If the relative humidity be such, however, that a rapid evaporation of the perspiration can take place, the temperature of the body may remain very nearly normal, even though the atmospheric heat be extremely high. In this way relative humidity is of value as a regulator of body heat, and becomes of supreme importance in diseases of the heart and kidneys where a free secretion and rapid evaporation from the sweat glands is absolutely necessary, not only to rid the system of its waste products, but to relieve the blood tension and functional activity of the diseased organs.

From these hasty examples, then, it may be seen whether we as physicians ought to neglect data of relative humidity, and whether, as has been claimed by meteorologists, relative humidity "gives results of no practical importance to the invalid."¹²

It is true we can derive little benefit from such data when they are taken apart from temperature; neither, as I shall show later, can we form data of absolute humidity when they are taken apart from the dew point. Temperature should never be omitted from consideration, but temperature is by no means the only factor that we must use; it is only the argument, so to speak, upon which the story of nature is based. Without doubt also we can ill afford, in estimating the clemency or severity of a climate, to omit the daily range of temperature. This range is often considered to depend upon the existing degree of absolute humidity, but absolute humidity is not of spontaneous origin, it is only a single factor, and a mediate one at that, in equalizing temperature. The true cause of the range of temperature lies back of absolute humidity, and depends ultimately upon the united action of many factors — the temperature, the amount of sunshine, the nature of the soil, and the direction, velocity and character of the winds.

To such an extent, however, are the winds modified by variations in the contour of the country, the hills and valleys, the forests, the lay of the land, whether it faces north, south, east or west, and its position in regard to the sea, that any single set of data which depends upon these local peculiarities, and can in a measure, however imperfect, reveal them, should be of especial value to us. Such data are offered in the ratios of vapor tensions, which are of interest and importance. The superficial objection then that has been raised, that relative humidity gives results fickle and of no practical value, because so profoundly influenced by local causes,¹³ should in itself be sufficient warrant for making use of relative humidity, if nothing else even could be adduced in its favor.

But relative humidity has still further interest for us. Suppose that into a warm atmosphere with a dew point nearly identical with the temperature of the air, that is to speak popularly, nearly "saturated" with vapor, there blows a cooler air; the temperature will

¹¹ Where shall we spend our summer? Gen. A. W. Greely. Scribner's Magazine, April, 1880, page 405.

¹² Moisture and Dryness, Chas. Denison, M.D., page 23.

be lowered, but the vapor tension will be reduced in a much greater ratio so that clouds may form, condensation of vapor will take place and dew be deposited, fog appear or rain fall. So, too, if into a cool atmosphere a warm moisture-bearing wind¹⁴ blows, the same cloud formation and aqueous condensation will take place. And not only is the amount of this precipitation important to health, its daily distribution, that is the frequency of dews or storms, is equally of value.¹⁵

So far, however, am I from maintaining that relative humidity is the most important element in estimating the relations of climate to health, or even a more important element than absolute humidity, that I believe the truth to be that we are not only precipitate in ascribing supreme importance to the weather in the maintenance of health, but too fond of generalizing from weather data that are incomplete and therefore misleading. No separate sets of weather, nor all combined, can adequately represent a climate in its health advantages. We must have also data belonging to the geographer, the chemist and the geologist. Life and its influences are not made up of discrete phenomena which can be abstractly discussed apart from every attending circumstance, as can experiments in a physical laboratory, and our daily status is merely the resultant of a vast correlation of conditions which do not and which cannot, in the existing order of affairs, work in any other than a connected manner, dependent the one condition upon the others.

I am not here extolling the advantages of any particular climate or locality, but even were I estimating comparative climatic values, I am sure I should give a place to relative as well as to absolute humidity, and should neglect neither.¹⁶ Nor am I constructing hypotheses to account for the causation of disease. I have no pet theories to weave into the very texture of my thoughts. I am simply searching after truth wherever it may be found, and can therefore accept as a contribution to my knowledge some sets of data which another might regard as a hindrance to the development of his theory.

As has been said by eminent authority,¹⁷ "it is significant of the state of public knowledge in respect to humidity that local writers use and all interested quote that phase of humidity which best suits their line of argument." This is no more applicable to enthusiasts praising pet localities as health resorts than it is to scientists who see confirmation of their theories in everything they agree to look at, but who do not agree to look at everything that is before them.

THE COLORADO ATTEMPT TO ESTIMATE HUMIDITY AND CLIMATE.

Of the theory of humidity devised by Dr. Denison of Colorado¹⁸ there is little to say, but that little should be very emphatic. The maps are inherently pernicious in their influence, although their brilliant

¹⁴ By moisture-bearing winds I do not restrict myself necessarily to winds bearing only vapor — they may bear also liquid water in fine suspension.

¹⁵ On the influence of forests upon evaporation and rain-fall, see B. E. Fornow, Chief of Forestry Division, Special Report in Report of Secretary of Agriculture, Washington, 1889, page 297, et seq.

¹⁶ In the comparative study, however, of the variations in monthly or seasonal influences upon disease where we already know the general agreement of absolute humidity, I regard change in relative humidity as of more importance than change in absolute humidity. See my paper on Phthisis and Pneumonia, Massachusetts Communications Massachusetts Medical Society, 1888, page 272.

¹⁷ Where shall we spend our winter? Gen. A. W. Greely. Scribner's Magazine, October, 1889, page 10.

¹⁸ Moisture and Dryness, a new Annual and Seasonal Climatic Maps of the United States, by Charles Denison, M.D., Denver, Colorado, 1885.

colors and the general air of official meteorological authority give them at first blush an apparent but fictitious value. Denver is made a Garden of Eden, but, unfortunately for science and for accuracy, the rating tables¹⁹ upon which the whole climatic theory depends are made by averaging unlike averages, by adding together such unlike data as averages of relative humidity and cloudiness expressed in per cents, and the product of absolute humidity expressed in tenths of grains, multiplied by an average percentage of relative humidity. The process is much like adding apples to pears, and expressing the sum in terms of plums, and there cannot be the slightest shade of reason why the system or the charts should give the least idea of humidity or of climate.

(To be continued.)

A CASE OF HOMICIDE IN WHICH THE LOCATION OF THE POWDER-BRAND ASSISTED IN ESTABLISHING THE INNOCENCE OF THE ACCUSED.²⁰

BY J. H. HALL, M.D. (HARV.), STERLING, CO.,
President of the Colorado Board of Medical Examiners.

On October 2, 1884, Dr. D. B. M. Fish, one of the medical examiners for the State of Massachusetts, reported, in the Boston *Medical and Surgical Journal*, a series of experiments by which he had determined the cause of the "brand" in gun-shot wounds. He was furthermore able to deduce, from its position, the manner in which the weapon had been held as regards the direction of the hammer. I report to-day, what is, so far as I have been able to learn by correspondence with Dr. Fish and otherwise, the first application of this knowledge to aid in determining the guilt or innocence of one accused of homicide.

In this case, the deceased, H., was shot through the head by M., and at the examination of the body, a scratch appeared upon the throat, from which slight bleeding had taken place. The daily press reported that M. had deliberately cut his victim's throat and then shot him; and, as a consequence, feeling ran high against the accused.

The scratch was proved to have been made by a fancy hair-pin which M. held in his left hand, he having been in the act of wrapping it up for a lady in the store at the time he was called to the door by his assailant. The brand was found entirely below the wound — an almost inexplicable fact to me at first sight. Then it was learned that, although it was dark at the time of the attack by H., several witnesses stated that M. had been in the act of striking over-handed at H. when the noise of the discharge was heard and the flash seen; but none of these witnesses could see the revolver. The evidence from the brand, showing that the weapon was wrong side up at the

¹⁹ A paper read before the Colorado State Medical Society at its Annual Meeting, June 18, 1890.

²⁰ To obtain the "rating mean" of humidity, Dr. Denison estimates the means of the relative humidity records of the Signal Office stations throughout the United States to be 67 per cent.; 67 per cent. of the absolute humidity in tenths of grains is then obtained for every degree of temperature, and the means of Signal Office data of cloudiness are calculated to be 44 per cent. One-half of the sum gives the "rating mean" for a given temperature, ignoring altogether the dew point. Compare with this "rating mean" one third of the sum of the actual records given of the above attributes for any place, and the difference, plus or minus, shows the rate of humidity of that place. The "rating mean" and sensible portion of this measure the rating records of the Signal Office stations read at the Colorado State Medical Society; their distortion is Dr. Denison's idea.

time of discharge, was substantiated by that of the manner in which it had been held in attempting to strike the blow.

It would seem to me that M. never could have been convicted upon the evidence produced, had he deliberately shot his assailant, as the latter had made repeated threats to kill him. However, this evidence, proving absolutely to the jury, as they have since informed me, that M. intended only to strike H. and not to kill him, and very adroitly handled by the attorney for the defence, Mr. Charles L. Allen, of Sterling, Col., assisted materially in making the acquittal a comparatively easy matter, in spite of the fact that the three attorneys for the prosecution attempted to prove that this evidence was of no value whatever. At the trial, several targets showing the location of the brand, with the different positions of the revolver, were shown. There was no evidence introduced in opposition, as the prosecution destroyed the targets they had prepared, for the reason that they were even stronger evidence than those shown by me.

The cause of this phenomenon is briefly this: the point of support of the revolver being below the line of application of the force generated by the burning powder, this force tends to cause the weapon to revolve about the point of support. The gases which impel the ball, being necessarily behind it, follow the new direction of the barrel after the ball has left it, and hence strike above the bullet-hole or to one side or below, as the case may be. In other words, the kick of the weapon does it. The powder stain and smutting may show all about the wound in some cases, but the brand, if distinctly marked, is always found as indicated above. I find that if a revolver be very dirty before the discharge, the old smut is often blown out in front of the ball, and stains on all sides, and thus obscures the point at issue. As proof of this explanation, Dr. Fish shows that, if the pistol be held in a vice, the brand is equally distributed about the bullet-hole, regardless of the position of the weapon, for here there can be no recoil. At a distance of a foot or more, the brand is commonly indistinct or absent. With a Winchester rifle (40, 82, 260), the brand shows very slightly above the wound; and with the left barrel of a No. 10 Colt shotgun, above and to the left. Here, of course, the line of application of the force passes much nearer the point of support.

It was objected, in this case, that M. might have been in the act of bringing his revolver "down to a drop," as is done by many in the West. Target No. 3 (shown when the article was read) made in this manner, effectually disposes of this idea, as it coincides precisely with the others. It is possible that the weapon might be moved with such rapidity that the brand would appear on the other side of the bullet-hole, being carried by, as it were, but certainly not with the ordinary speed of the hand in such a manner of shooting.

Two matters I wish to mention further. I had the targets prepared by Mr. William H. Gleason, under my direction, before telling him of the object in view, that the jury might not believe that the result was modified by my own shooting. I also made at the examination, for exhibition in court, a drawing of the wound, but would, under similar circumstances in future, recommend that it be photographed.

While, as Dr. Fish states, it would be possible to make a pistol with the centre of gravity in such a

place that this rule would be reversed, in point of fact, he states, none are so made; so that the rule applies universally.

REPORT OF PROGRESS IN GYNECOLOGY.

BY F. H. DAVENPORT, M.D.,
Instructor in Gynecology, Harvard Medical School.

EFFECT OF THE INFLUENZA ON DISEASE OF THE FEMALE GENITAL ORGANS.

GOTTSCHALK¹ is able from cases which he observed in his own practice, to verify Biermer's statement that, as a result of the influenza, metrorrhagia sometimes occurred, and in cases of amenorrhoea menstruation was re-established.

In four cases, the bleeding occurred either on the first or second day of the disease, was quite profuse, accompanied by backache, and, in two cases, with a frequent desire to urinate. The hemorrhage lasted five to eight days. Examination showed a marked swelling of the uterus and a well-defined softening of the walls, so that they suggested the softening of pregnancy. The mucous membrane was extremely sensitive to the passage of the sound, and softened, but without roughness. The canal was lengthened from one to one and a half centimetres.

The author considers these hemorrhages as caused by an acute inflammation of the uterine mucous membrane, and not of reflex origin from the appendages. As proof of this, he cites a case where, in April, 1889, he had removed the appendages, and the patient had not menstruated since. She came down with the influenza on December 17th, and immediately was taken with uterine hemorrhage, which lasted as long as in the other three cases.

Gottschalk found that pregnant women were as susceptible to the influenza as non-pregnant women. In two cases abortion followed; once at the third month, and once at the fourth. One woman, in the ninth month, had pains for four days, and the os uteri dilated so as to easily admit two fingers, but the pains ceased with the recovery from the influenza. The author thinks that in these last cases an acute inflammation of the uterine mucous membrane or the decidua was present, which, in the first half of pregnancy, easily results in abortion.

Dr. R. Müller gives, in this article² the results of his experience on this subject, from the study of fifty-one cases. His attention was drawn to the occurrence of hemorrhages from the genitals, and his conclusion is that the influenza had a direct causal effect in their production. The flowing occurred during the intermenstrual period, usually in the very first days of the influenza, and was, as a rule, long continued and stubborn to treatment. In those cases which had been previously healthy as regards the genital organs, the flowing came on without subjective symptoms. In those, on the other hand, which had been under treatment for trouble with the sexual apparatus, there were pain in the small of the back, desire to urinate, and a generally worse condition of the old trouble. In both classes of cases he found increased temperature of the vagina, swelling of the cervix and of the uterus, and increased sensitiveness of the latter. The pain, on the gentlest palpation, was often intense. Only once was any trouble found with the appendages.

¹ Cent. für Gyn., No. 3, 1890.

² Cent. für Gyn., No. 17, 1890.

Of the fifty-one cases of women affected with influenza under the author's observation, three were pregnant. Of the remaining forty-eight, forty-five suffered from metrorrhagia. Of the three which did not, one was a girl of sixteen, who had menstruated only a few times, and then only for a day at intervals of two to three months; another was a young woman who had given birth to a child twelve weeks before, and was nursing it. In her case a very profuse leucorrhœa came on, which ceased as soon as the influenza was over. Of the three women who were pregnant, in two it was interrupted; one at eight weeks, the other in the eighth month.

CHANGES IN THE ENDOMETRIUM IN CASES OF CARCINOMA OF THE CERVIX.

While it is the duty of the surgeon in cases of malignant new growths to save the patient from certain death by a radical extirpation of the disease, the ideal of operative treatment is complete restoration to health with preservation of normal condition and function of the parts.

These considerations are of importance in beginning cancer of the cervix. The question has been much discussed whether a total extirpation of the uterus is necessary, or whether in the very earliest stages of the disease a supra-vaginal amputation of the cervical portion suffices to effect a cure. An important factor in the decision of such a question is the statement of Abel that, in a large number of cases of cancer of the cervix, the mucous membrane of the body has undergone sarcomatous degeneration. Out of seven cases he found three which were sarcomatous. If this proportion should hold, the question of choice of operation would be superfluous.

To determine the truth of these observations, E. Saurenhaus³ has examined fifty uteri which had been removed for diseases of the cervix and vaginal portion. The histories of the fifty cases are briefly given with the macro- and micro-scopical changes, with in general the following conclusions:

As a negative result, in not a single case was an endometrium found which at all approached the normal. In many cases even the muscular structure showed changes which were probably due to the chronic irritation of the cancer, changes which corresponded to those in chronic infarction of the uterus.

In general they could be divided into two classes, those principally in older women at the time of, or after the menopause, which showed atrophy of the mucosa, and those in younger women which showed a thickening and increase of glands, interglandular substance, or both. For the details of the changes the original article should be studied. The important conclusion is stated that the changes in the endometrium in these cases differ in no respect from those glandular and cell changes which occur in every case of simple endometritis, and give no ground for any suspicion of sarcomatous degeneration.

Rüge as a result of long years of observation has come to the same conclusion.

THE UTERINE MUCOUS MEMBRANE DURING AND AFTER MENSTRUATION.

V. Kahlen⁴ considers that the different opinions with regard to the conduct of the uterine mucosa dur-

ing and after menstruation arise from faulty methods of examination. He asserts that the question of the desquamation of the superficial epithelium can only be decided from carefully imbedded preparations.

He has made his studies from specimens fresh from the cadaver, hardened in Müller's fluid and imbedded in celloidin. According to his investigations, the epithelium is always for the greater part thrown off. The presence of epithelium and tissue from the mucous membrane in the middle of blood-clots occurring during life proves that such changes are not due to post-mortem degeneration. Not alone is the superficial epithelium thrown off, but also a great part of the mucous membrane which is filled with blood. The desquamation does not all occur at the beginning of menstruation, and there may be numerous portions intact even towards the end, facts which explain conflicting views. The escape of blood results from the throwing off of the mucous membrane, but whether it occurs per rhexin or per diapedesin, v. Kahlen's investigations furnish no proof. There was no small cell infiltration of the tissue, nor any enlargement of the gland cells.

Examination of the uterine mucous membrane after menstruation showed invariably desquamation of the upper layers of the mucous membrane, and an increase in the size and number of the blood-vessels.

ELECTRICAL TREATMENT OF UTERINE FIBROIDS.

Plicque⁵ lays especial emphasis on the following points in A postoli's method of the treatment of fibroids. One should never exceed at the first treatment forty to fifty milliamperes; at subsequent seances the intensity can be carried quite rapidly to eighty and one hundred, and even more if improvement does not begin. If necessary do not hesitate to use electricity during hemorrhage. If the patient has to work, do not give more than one treatment a week. The negative galvano-cauterization is especially indicated in cases of fibroids complicated with amenorrhœa, dysmenorrhœa, or atresia of the cervical canal. With the negative pole the intensity should be less, and the application shorter.

Galvano-puncture is a last resort for fibroids which are especially stubborn to electrical treatment. In these cases it is well to begin with thirty to forty milliamperes and very gradually increase to fifty or sixty. Especially sensitive patients should be anesthetized. Metrorrhagia is the symptom most easily relieved, and peri-uterine inflammations usually show rapid improvement, while reduction in the size of the tumor is sometimes very difficult to secure. In fortunate cases a reduction of a quarter to a third may be obtained by the galvano-cauterization and still more with the galvano-puncture.

NEW OPERATION FOR UTERINE MYOMATA.

Dr. G. R. Fowler⁶ describes a new operation for the cure of uterine myomata, which he calls intra-capsular sloughing through an abdominal incision. He was led to apply it as a definite method of cure through an accidental experience. In attempting the removal of the ovaries in a case of a large fibroid, they were found to be so bound down as to preclude the possibility of their removal, and in the course of the operation the tumor was wounded. The hemorrhage

³ Zeits. für Geb. und Gyn., xvii Band Heft, 1880.
⁴ Beiträge für Geb. und Gyn., 1889.

⁵ Gaz. des Hôpitaux, November 16, 1889.
⁶ New York Medical Journal, June 7, 1890.

which was persistent was only checked by the use of the thermo-cautery. The abdominal wound was left open, and the process of sloughing initiated by the cautery did not cease until complete intra-capsular separation of the tumor had taken place and the broken down mass had been extruded through the abdominal opening, which process was completed and the wound perfectly healed at the end of six weeks.

Encouraged by this experience Dr. Fowler followed the same course in three other cases which were suitable with complete success. In no case was there any suspicion of sepsis during the course of the treatment.

ELECTRICITY IN CHRONIC PELVIC INFLAMMATORY DISEASE.

Apostoli and his followers have claimed that cases of salpingo-ovaritis can be cured by electricity. In his own words: "It is sovereign in catarrhal salpingitis, only calmative in tubercular salpingo-ovaritis, and in certain pus tubes may be of great service." These claims to the curative value of electricity in these cases, Dr. Baldy⁷ considers extravagant, and in the article under consideration gives his reasons. The salient points are as follows: First, it is evident from Apostoli's description of cases treated, that by cure Apostoli meant that he had cured the symptoms, but not the organic lesions, and his account of what he found at the final examination showed marked organic changes. Some of the disciples of Apostoli go farther than their master, and claim the absorption of exudations and adhesions.

Second, Dr. Baldy has had opportunity to follow many cases very carefully during electrical treatment, and to examine the patients during the continuance and to the end, and to see many of them after they had been pronounced cured, or had ceased to come for treatment. He says, "In all this time I have failed to observe a single cure of the disease." He has observed relief in some cases, but even that has not been permanent, and on the other hand, he has seen patients made worse by the treatment.

After a detailed history of one typical case where electricity was faithfully tried and failed and the patient finally came to operation, Dr. Baldy gives his theory of what electricity does accomplish. He says: "Electricity properly and carefully applied will in time relieve the pain of the pelvic peritonitis, but under no circumstances can it influence for the better the resultant chronic adherent salpingitis of the original attack. Electricity is a particularly slow method of giving temporary relief, and if the physician wishes to cure the patient permanently, he must remove the uterine appendages." This, of course, applies only to a small proportion of the cases of chronic adherent salpingitis; the majority can, with ordinary hygienic and dietetic care combined with slight medication from time to time, live a comfortable life.

In conclusion, he says that the place he gives electricity is simply that of a therapeutic agent which will mitigate, but which will never cure. He classes it with glycerine tampons, hot water injections, purgatives, etc., and considers it the least valuable of them.

THE ULTIMATE RESULTS OF LAPAROTOMY FOR THE REMOVAL OF DISEASED APPENDAGES.

Dr. H. C. Coe,⁸ in this article, considers the im-

portant question of the condition of patients who have been the subject of laparotomy for diseased appendages, at a period of one, two or five years after recovery from the operation. The permanent ill-effects which may follow, he classes under two heads, physical and psychical.

As regards the psychoses, some competent observers hold that there is a direct relation between the operation and the subsequent mental aberration which sometimes occurs.

The physical results may be general or local. The general disturbances are the various neuroses, circulatory abnormalities, such as true cerebral hyperæmia, and various visceral disturbances.

He calls especial attention to the local or intrapelvic complications, and considers that these are due to indurations or adhesions which may have existed before the operation, or may be the result of localized peritonitis following it. If pre-existing and separated at the time of operating, they are very apt to reform. As regards new adhesions forming, as a result of localized peritonitis, this must be common, and the author considers that as yet we possess no sure means of avoiding them.

He gives the histories of eight of his own cases in which the patient was either no better, or decidedly worse, after the operation. He says, "If, with my limited experience, I have observed so considerable a proportion in which laparotomy is not followed by permanent benefit, at least as far as regards the relief of pain, those operators, who number their cases by hundreds, could, if they would, add much to our knowledge in this direction."

Reports of Societies.

NEW HAMPSHIRE MEDICAL SOCIETY.

REPORT of the Ninety-ninth Anniversary, held at Concord, N. H., June 16 and 17, 1890.

After the routine business of the Society was attended to, the first paper read was by DR. GRANVILLE P. CONN, of Concord, N. H., the subject being

RAILWAY HYGIENE.

He says: As an illustration of the fact that the public are becoming critical on this subject, I will quote from the report of the Railroad Commissioners of the State of Massachusetts, for the year 1889:

"One of the crying evils of railroad travel at the present time is foul air. The amount of air-space in a car is very small, considering the number of people occupying the car; and if no fresh air was admitted, would be used up in a few minutes. . . . Death from burning is the most horrible death a man can suffer; and it is on account of the torture connected with it, rather than its frequency, that we urge so strongly the adoption of locomotive steam-heating systems. It is certain that in railway travel much more of life has been destroyed by poor ventilation of cars than by fire. . . . On many roads the ventilation of cars is unwarrantably neglected, to the injury of their business as well as to the injury of the health of passengers."

Such conditions as might give rise to the development of zymotic disease should not be allowed to exist on lands owned and controlled by corporations, any

⁷ Medical News, March 22, 1890.

⁸ Medical Record, April 19, 1890.

more than about the premises of the individual. It is difficult to deal with corporations, however, in regard to these matters, as there is no well-defined department with which to confer, and hence no systematic supervision over them.

At present, train-men give little or no attention to the atmospheric conditions that obtain in a car. They should have plain, comprehensive instructions on matters of this kind; and I hope it will not be very long before something of the kind will be published in pamphlet form, after the style of the series of health-primers which have developed interest in hygiene and sanitation.

At some points, the boom that is made in making a place for invalids fills the cars with many people with positive evidence of phthisis or syphilis. If catering to individuals is to be indulged, lines running to such resorts should set apart an invalid's car.

Even the Pullman and the boudoir car are often unclean and unventilated, and have filthy closets; all of which destroys the prospective comfort of a journey.

Within the last twenty-five or thirty years great advance has been made in the road-bed, cars, stations, locomotive, power-brake, etc.; but in some sections of our country, but little has been done in the advancement of railway surgery, and persons receiving injury from an accident to-day would receive at the hands of the corporation substantially the same treatment as was given twenty years ago. This is creditable neither to the road, people along the line, nor the profession.

DR. WALLACE RUSSELL, of Concord, reported a case of laparotomy:

UNILOCULAR PAPILLOMATOUS CYST OF THE LEFT OVARY.

The woman was a widow, aged forty-six, childless. Seen first, September 18, 1889. Health never equal to average woman; had suffered more the last three years.

Physical Examination.—Facies sallow; respiration short and labored, after walking; pulse weak but regular; no valvular lesions; great weakness generally.

Abdominal Examination.—Dulness in left lumbar, inguinal and suprapubic regions; some ascitic fluid; umbilical measure, thirty-eight inches; no difference in measure of two sides. Internally, found the uterus retroverted and immovable; fundus enlarged; a bloody serous discharge flowing out. The sound seemed to meet with obstruction, but was passed four and a half inches. The same immobility of parts in change of posture as in pelvic peritonitis.

September 22d. A small fibrous polypus was presenting at internal os.

September 23d. The polypus was removed with écraseur.

Patient kept her bed three weeks. Digestion improved; abdominal measure one inch less; pelvic pains relieved. Internal treatment, hot douches, absorbents and alteratives. Urinary analysis gave negative results. Diuretics availed but little.

November 25th. Attempted to shake the furnace; felt something give way near the umbilicus. Peritonitis developed.

From November 30th to December 14th, blood was passed with the stools nearly every day. Measured forty-two inches; as the inflammation subsided, the

ascitic fluid lessened, till she measured thirty-eight inches again.

January 1st. Discovered a cyst. Temperature remained above normal during January. General condition on the retrograde. Steady increase in size, with marked difference in appearance. On consultation, an exploratory incision was advised, as the only means of correct diagnosis. It was thought that the growth was malignant. Patient insisted that any growth should be removed.

February 15th. Dr. Mary Smith, of Boston, operated. A tumor was discovered bound by many adhesions. Sixteen pounds of dark fluid were removed. Evidently there had been a hemorrhage within the cyst. The cyst adhered to omentum, cecum, vermiform appendix, several coils of small intestine, bladder and front walls of uterus, which was pushed over against the rectum. Operation required considerable time; but few ligatures were used. There was considerable oozing from the abraded surfaces. Copious irrigation of boiled water, from 105° to 120°, was used till the water ran clear and the patient's vital forces in a measure restored. Quite a little water was left in the cavity. Glass drainage-tube was inserted, and removed next day. The wall of the cyst was very thin in some places, and contained firm bands in others. Numerous polypi, from half an inch to two and a half inches in length, were clinging to the sac internally.

During the operation, which lasted two hours, some points arose of special interest to me:

When the fluid was withdrawn, the heart's action was stronger, more volume to the pulse. As the operation continued, the pulsations grew more frequent and weak, and at times would lose the radial pulse. Brandy was freely used, but it seemed that the patient must succumb. Immediately after using the hot water, however, the bleeding was checked, and the symptoms of shock, which were present to an alarming extent, were at once relieved by the hot water. What is the action of this hot douching of the abdominal cavity, besides cleansing the parts, and as a haemostatic? Its action is so sudden, it certainly could not be by absorption. Since then, the subject has been ably written upon by Dr. Abbott, of New York, in the April number of the *Obstetric Journal*, and I would call the attention of those who have not read the article to it.

The next day after operation the abdominal cavity was again washed out, with gratifying results; after which the tube was removed and the suture tied.

February 25th. Sutures removed. Healing by first intention. Convalescence was slow, as she had not only to recover from the operation, but from months of weakness previous to the operation. The ice-coil was used to allay pain.

DR. A. H. HARRIMAN, Laconia, reported a case of COMBINED INTRA AND EXTRA TWIN PREGNANCY.

November 23, 1889, I was called to attend Mrs. W., aged thirty-two, who was in labor for the first time. Lying on the bed, her abdomen was unusually large, and presented an appearance I never witnessed before, namely, just above pubes a firm, rounded eminence, which I took for a child's cranium, presented itself, raising the integument and underlying tissue the thickness of one's hand. In the right lumbar region, directly opposite the umbilicus, a smaller part

appeared; and directly above the umbilicus, at the fundus, two still smaller parts, or points, in close proximity were presented. I cannot say positively what these latter parts were, although the parietes were stretched to an enormous thinness. I supposed I had an ordinary case of twin pregnancy to attend.

Labor continued from 10 P.M. in the usual way, until 5 o'clock next morning, when a seven-pound living female infant was born, followed very soon by its placenta and secundines. All pain ceased, but evidently another child, apparently full grown, was in the abdomen.

I saw her about 8 P.M., November 24th, when very strong pains were putting in their work, but after waiting until 2 o'clock, A.M., November 25th, I decided to call assistance. We administered chloroform, and each in turn passed a hand into the uterus, but it was entirely emptied, and, between our hands, in making bi-manual manipulation, we found a child, probably as large as the one born — extra uterine, head above pubes of mother, back to front of mother. The limbs, hands and feet were easily recognized through the intermediate tissues. No signs of life at any time in the extra-uterine child. After recovering from the chloroform very powerful pains followed, which were quelled only with very large doses of opiates. These recurred for eight nights with equal frequency and force, leaving the woman comfortable during the day-time. At the end of twelve days very little pain existed.

The treatment has been entirely expectant, and, aside from these pains, there have been no untoward symptoms. At the end of two weeks a very appreciable diminution in the size of the tumor had occurred. In February, 1890, the tumor was about the size of a large-sized coconut. She has been well since. All knowledge of her condition has been kept from her, owing to over-zealous action on the part of husband and friends.

As near as I can learn, the course of gestation proceeded in a quiet manner, except, about the fourth month, she had considerable pain in her abdomen, and the last eight weeks were painful, and difficulty of locomotion was experienced.

For treatment of these cases I would suggest — in case of rupture or presence of hectic discharge — if all is well and one concludes to operate, do the secondary operation not earlier than the fourth, or better, the sixth month or later.

PROFESSOR C. P. FROST, of Dartmouth Medical College, read a paper on

PTOMAINES.

Definition. — Chemical compounds which are basic in character, and are formed during the putrefaction of organic matter. They may be derived from either animal or vegetable decomposition. Some are poisonous, others are not. All the poisonous products of putrefaction are not ptomaines.

Some of them resemble the vegetable alkaloids very closely in their effects on the animal organism. They are doubtless formed by the agency of bacteria. Different ptomaines are formed by different bacteria. Their formation depends on the condition in which the putrefying material is placed. They are transition products of decomposition, and may have a very brief existence, so that substances highly poisonous at one hour may be entirely harmless the next hour.

Ptomaines are frequently developed in connection with articles of human food, such as milk and its products, fish, etc. The ptomaine tyrotoxin is found in ice-cream — myatotoxin in mussels.

The study of the ptomanies enables us to understand more fully the manner in which micro-organisms cause disease.

It is now too late to question the relation of germs, microbes, etc., to disease as causation agents. Patient research has established that to be true in regard to many diseases; still the question arises, How do these micro-organisms produce disease? Several theorists have proposed to answer this question. First, it was attributed to deoxidation of the blood. Second, the mechanical interference theory — the bacteria causing disease by accumulating in large numbers in important organs, and thus mechanically interrupting their functions. Third, the theory that disease was due to the consumption of the proteids by the bacteria. Fourth, that the bacteria destroy the blood cells, or cause them to disintegrate rapidly. Fifth, that the disease is due to the action of chemical poison, developed by the action of bacteria on the fluids or solids of the body — that is, to the action of ptomaines; this last theory seems at present to be the true one, and capable of being conclusively demonstrated to be correct. Thus we reconcile the views of those who held that disease was due to a chemical poison rather than to a germ, with the views of those who held exclusively to the germ theory.

DR. GEORGE COOK, of Concord, reported

THREE CASES OF SURGERY.

The first, that of a young man, aged twenty-three, admitted into hospital July 2, 1889. Probably injured himself by hard work while young. When fifteen years of age, the right forearm began to pain him. This was followed by swelling. Abscesses formed, which were either opened by surgeons or had opened themselves. He had been in other hospitals and had suffered many things of many doctors.

The palmar aspect of the right forearm was covered by cicatrices. Near median line, two inches from wrist, was an opening from which a piece of bone protruded. A portion of the radius, four inches long and an inch wide, was removed, which evidently had been detached for some time. The wound dressed by drainage-tube and iodoform gauze. July 4th, the tube was removed. July 6th, the wound was nearly healed, and in a few days patient was discharged well.

I have seen the man within a few days. The arm is sound, and he has been able to work every day since. The point of interest is, that we were able to do what nature had been trying to do, namely, to get rid of a fragment of dead bone. When this was done, the patient got well.

The second case was that of a boy, aged seventeen, injured while coupling cars, resulting in a compound comminuted fracture of all the fingers but the little one. The distal ends of the four metacarpal bones were all exposed, the integument on back of hand destroyed up to a line with distal end of metacarpal bone of thumb.

Accident occurred August 13, 1889. Immediately brought to hospital. Little hope was had of saving any of the wounded parts; but, to try to save as much of the hand as possible, the parts were put in as good position as possible and dressed with iodoform gauze,

and hand put into a splint. August 22d, we amputated the distal extremity of metacarpal bone of the thumb and three fingers, and the whole wound was left to granulate. It healed rapidly. September 30th, patient was discharged well.

The delay in operating gave us a chance to save all that could be. The young man has a very useful part of a hand left. With the little finger and the remains of the metacarpal bone of the thumb he can pick up a pin.

The third case, which is one of considerable interest, will be reported later.

DR. W. D. CHASE, of Peterboro, reported a case of DIFFUSE CALCIFICATION OF THE MUSCULAR SYSTEM IN A CASE OF FRACTURE.

A man, aged sixty-three, strictly temperate, on the morning of August 3, 1889, in jumping a distance of about four feet, sustained a severe injury to his left leg, which I found to be a compound fracture of the tibia and fibula just above the malleoli, the tibia protruding half an inch. The bones were brought into apposition, the wound united by a few stitches and adhesive plaster and bandaged with carbolic gauze, and the limb was placed in a splint, the whole kept moist with carbolic acid. The wound united nearly its whole length by first intention. Health of patient good. In about ten days, the new tissue gave way with extensive sloughing of the skin and tissues. A small portion of the upper fragment of the tibia became denuded of the periosteum.

At this time, Dr. G. P. Conn, of Concord, was called in, who, August 17th, excised about half an inch of the tibia a little above where the periosteum was destroyed. Bones were brought into apposition, and limb placed in wire splint and wound washed two or three times daily with a one-four-thousandth solution corrosive chloride. Wound did well, until after about two weeks it ceased to heal and sloughing commenced. In a short time, the whole ankle and the tissues up the limb became boggy. There was now noticed a diffuse calcification of the arteries. This had not been observed before, and we are quite sure had developed since the accident.

Dr. Conn amputated between upper and middle third. The ligatures were tied with difficulty, on account of vessels crumbling; but the vessels were finally secured by including a mass of muscular tissue. Dissection of the ankle showed that not a particle of bony material had been thrown out at the end of the tibia of fibula.

The wound was treated antiseptically. Tonics were given the patient, —syrup of phosphate of iron, quinine and strichnine were prescribed. Delirium developed, and he seemed like one intoxicated; but was soon restored after the stimulants were withdrawn. The wound healed.

During convalescence the arteries became less firm. To-day there is an atheroma of the radial arteries, but cannot find it elsewhere.

The case is of interest from the fact that calcification of the vascular system may, in some instances, account for the non-union of fractures.

DR. L. G. HILL, of Dover: I would like some one to explain why calcification did not go on higher, after the amputation.

DR. CHASE: After amputation, there was no necessity of having new bones, and of course the lime for the formation of new bones was absorbed.

DR. THOMAS HILAND, of Concord: These cases reported by Drs. Cook and Chase illustrate a fact experienced by surgeons; that you have to treat the lower extremities far differently from the hands and arms. In case of injury to the latter, nature will do most of the work of healing without much aid on the part of the surgeon. A wound of the lower extremities is more difficult to heal. This is because the arteries are more in number, and hence the circulation and vitality of the upper extremities are better.

DR. H. K. FAULKNER gave statistics in regard to

THE RECENT EPIDEMIC OF DIPHTHERIA IN KEENE; and the subject of diphtheria was discussed to quite an extent.

DR. I. J. PROUTY, of Keene, opening the discussion, gave his experience during the epidemic: I was called to see a case of a boy about twelve years old. On examination of the throat, I found every evidence of tubercular tonsillitis. Soon after, I was called to see a sister of the boy. In her throat, I found that peculiar dirty-white membrane characteristic of diphtheria, and reported it as such to the Board of Health. In about a week more, a younger sister — a child of three or four years — was taken; and this was a case of tonsillitis nearly as typical as the first. Between two and three weeks, I was called to see the mother; and here again was the peculiar membrane of diphtheria. The question I wish to raise is this: Were these cases all diphtheria, or were they two different cases, — the first and second being tonsillitis, and the third and fourth diphtheria?

Further discussion was had as to what diphtheria is.

PROF. C. P. FROST: I believe there is a specific germ of diphtheria, and without that specific germ we cannot have diphtheria.

DR. E. F. MCQUESTEN, of Nashua, in reference to treatment of the disease said, that he treated diphtheria antiseptically. He had tried tracheotomy and also intubation. Where he had performed tracheotomy, he had lost every case; but the result of intubation was that out of six cases on which he operated, he lost but one. "I have also used the spray; as, of course, the patient can breathe better in moist than dry air."

DR. THOMAS HILAND, of Concord, read an excellent paper on

MEDICAL MEN,

and one worthy of being reported in full, but space forbids more than the following extract:

"If our education was completed when we received the M.D., very imperfect would it be; but I can truly say that, in our Middle and Eastern States, young physicians, and old ones, too, are noted for their development year by year, so that I consider it a great privilege to secure an old gentleman in consultation to guide my youthful powers.

"It would be unreasonable to expect the study of medicine to get rid of all selfishness, all small, mean actions and thoughts; but its tendency is to enoble, and suppress dishonorable words and actions.

"The study of medicine opens to view the whole range of natural sciences, the nature of thoughts and actions, the beginnings of life, the finite and the infinite, and it is not strange that the most noted names in the scientific and literary world are those of physicians, to whose names belong so many honored titles that the modest one of M.D. is forgotten.

"I pity the person who tries to confine his studies and practice to the teachings of one man, however distinguished he may have been, for it dwarfs and narrows. It is the man versed in a variety of ways and means, that shows fertility in resource, that makes his reputation by his own individualism, his own untrammelled genius. Can we search out a single fact, the giving it to our fellow-workers gives us more pleasure than stowing it away for individual use; and he who postpones every joy until the indefinite future forgets that we have only to-day, and that good done to others is reflected."

The subject of the president's address was

INHERITANCE OF DISEASE.

The opinion prevails that diseases are transmitted as an inheritance from generation to generation. This opinion is fallacious. Literature and statistics are wanting. To prove it, there are no positive proofs on either side. There are no principles and laws of heredity whereby we may estimate and measure the probability or possibility of any given condition or disease to any given patient. Generalities and conclusions must be presented rather than particulars of proofs and evidences.

Nature always tends toward perfection of the original plan. She curves it only by force, and is ever vigilant to eradicate perversions and modifications.

Notwithstanding the multiplicity of our ancestry and the complexity of its various lines descending to and meeting in a given individual, the species is preserved according to general plan. Nature never abandons any of its characteristics, either general or particular. No original faculties are lost nor are new ones added, although the original ones may be modified by natural or artificial selection. The development and selection theories are true only in the modification of natural and original traits, qualities, faculties, form and features, not in their destruction or even in their perversion. If imperfections do seem to pass on to one or two generations, the imperfect ones go down before the first epidemic. Nature does not wish their kind reproduced.

Disease is for a purpose. It is the decay and death of the imperfect individual, that the species may advance a step toward perfection. Nature does not perpetuate these imperfections, imbecilities, encumbrances and damnations. It is exactly what she will not do. The attempt, even, is contrary to common sense, contrary to natural law, contrary to divine law, contrary to perfection of the species, contrary to the best interests of the human race, contrary to evidence, and contrary to the facts.

The officers elected for the ensuing year were: Dr. L. B. Howe, Manchester, President; Dr. M. W. Russell, Concord, Vice-President; Dr. G. P. Conn, Concord, Secretary; Dr. D. S. Adams, Manchester, Treasurer.

— The importance of a careful disinfection of the surgeon's hands is expressed by Bergmann in the following words: "Infection by contact with the physicians' hands plays a principal part in the etiology of diseases of wounds, and the much-prized skilful hand of the surgeon may bring the greatest harm with the tenderest touch."

AMERICAN OPHTHALMOLOGICAL SOCIETY.¹

Dr. Howe also read a paper on

LEGISLATION FOR THE PREVENTION OF BLINDNESS.

As nearly one-fifth of all the blind in the various asylums are there because of ophthalmia neonatorum, and as nearly all these cases could be cured if seen in the very first stages of the disease, therefore the writer urged the necessity of requiring nurses to report promptly every such case to some proper medical officer. In other countries stringent regulations have been adopted in this respect concerning the duty of midwives, and it was deemed in every way desirable to obtain here, also, as far as possible, the enactment of a law similar to that recently passed by the legislature of New York. This is as follows:

SECTION 1. Should any midwife or nurse having charge of an infant in this State notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such midwife or nurse so having charge of such infant, to report the fact in writing within six hours to the nearest health officer or some legally qualified practitioner of medicine of the city, town or district in which the parents of the infant reside.

SECT. 2. Any failure to comply with the provisions of this Act shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months, or both.

SECT. 3. This Act shall take effect on the first of September, 1880.

PURULENT OPHTHALMIA,

by DR. J. A. ANDREWS, of New York.

It has been claimed that the gonococcus was the cause of gonorrhœa, and that purulent ophthalmia was due to the same cause. The writer had made a number of examinations to see if the gonococcus were always present in these two affections. He had found the gonococcus in all cases of acute urethral gonorrhœa. In one hundred and forty-four cases of chronic urethral gonorrhœa he had found it in one hundred and eight cases. In the purulent ophthalmia of adults the gonococcus was found in all cases. In the purulent ophthalmia of the new-born it was found in all cases, one hundred and twenty-two in number. In the purulent ophthalmia of infants between the ages of two and three months, it was found in three cases out of nine examined. This makes three hundred and sixty-four cases examined, with the discovery of the gonococcus in three hundred and twenty-two. In nearly all cases the staphylococcus pyogenes aureus was also present.

In the treatment of purulent ophthalmia the uninterrupted application of cold washing with a saturated solution of boric acid and the use of a solution of nitrate of silver not exceeding 2% was urged. The solution of nitrate of silver is to be applied once or often during the day, according to the indications. If the discharge is not profuse, once a day is sufficient. If the discharge and swelling increase, the application may be made more frequently. Nitrate of silver is not well borne when there is little inflammation. The writer had found experimentally that a 2% solution of nitrate of silver destroyed the infective properties of the pus in from six to ten seconds.

Dr. Andrews also exhibited a drawing of

CYSTLIKE BODIES OF THE CONJUNCTIVA.

These occurred in a child five years of age, whose mother and brother had had trachoma. The child it-

¹ Report of the Twenty-sixth Annual Meeting, July 16 and 17, 1880. Concluded from page 138 of the Journal.

self had no affection of the cornea or trouble with the eye. The microscope showed that they consisted of hypertrophied conjunctival tissue.

A FORM OF XEROSIS,

by DR. CHARLES W. KOLLOCK, of Charlestown.

The author described a form of disease commonly seen among weak and scrofulous colored children, which differed from xerosis as commonly seen in that the conjunctiva is never contracted; the cornea, although more or less affected, is never destroyed, and, under proper treatment, recovery takes place.

Dr. Kollock also reported

TWO CASES OF GLAUCOMA

presenting certain interesting features. In one case (age fifty years), iridectomy was performed, but the operation was followed by increased tension lasting two days. A four-grain solution of eserine was then instilled every hour. Under this, the tension rapidly fell to normal.

DR. F. W. METTENDORF, of New York, reported a case of

EMBOLISM OF THE UPPER BRANCH OF THE RETINAL ARTERY, WITH NORMAL VISION,

in which, owing to a peculiar anatomical arrangement, the macula lutea was supplied by the lower branch of the retinal artery. In the lower part of the field vision was absent, but in the remaining parts of the field it was normal. The treatment consisted of pressure, massage, and digitalis. Vision is now returning in the lower portion of the field.

A CASE OF RECURRENT IRIDO-CHOROIDO RETINITIS,

by DR. SAMUEL THEOBALD, of Baltimore.

Ida R., aged twenty-five, was seen July 8, 1889. Her general condition was fairly good. There was no evidence of congenital or acquired syphilis. She was suffering from recurrent attacks of inflammation in the left eye, which she said had begun two years before, and had destroyed the sight of that eye six weeks before coming to the hospital. The eye had evidently been the seat of severe irido-choroido retinitis. The right eye showed no signs of disease. Enucleation of the left eye was strongly urged. This was declined. She was put on small doses of iodide of potassium, with instillation of atropia to the affected eye.

December 6th she again came to the hospital, having had an attack of inflammation in the right eye three weeks before. The eye was somewhat improved $V = \frac{15}{100}$. The left eye was at once enucleated, and atropia applied to the right eye. The next day the ophthalmoscope showed that there had been a mild attack of iritis, and slight inflammatory changes could be seen in the retina. Iodide of potassium and biniodide of mercury were ordered, and the eye slowly improved. December 23d $V = \frac{15}{100}$.

January 3, 1890, another attack of inflammation suddenly appeared without apparent cause. $V = \frac{1}{100}$. The iodide was increased to five grains every three hours, and a large blister applied to the nape of the neck. January 8th, vision had improved to $\frac{15}{100}$, but there was evidence of commencing iritis. The iodide was now substituted by hydrarg. biniodide gr. $\frac{1}{2}$, three times a day, and application of atropia to the eye. The eye steadily improved, and by January 28th $V = \frac{15}{100}$. February 11th the inflammation recurred.

By March 10th this attack had been recovered from. Another relapse occurred March 28th. As the attacks seemed to recur with a certain degree of regularity, quinia was tried. Under this there was improvement. May 28th there was a most severe attack. June 13th tension for the first time was found above normal. The condition of the eye steadily grew worse, and June 24th iridectomy was decided upon as a last resort. It was found impossible to grasp the iris with forceps, and, as a result, the intended iridectomy was converted into a simple sclerotomny. The effect of the operation was most satisfactory. July 7th she left the hospital, suffering no pain; but the vitreous was as cloudy as before, and it was impossible to determine that there was even light perception.

Syphilis could be almost certainly excluded in this case. The most probable explanation is that the inflammation was through the medium of the sympathetic or trophic nerves, and was dependent upon pathological changes in the ganglionic changes which have to do with the nutrition of the eye.

A CONTRIBUTION TO OCULAR TUMORS,

by DR. W. H. CARMALT, of New Haven.

Four cases of ocular tumors were reported, two of sarcoma of the conjunctiva and two of glioma. One of the latter was a case of double glioma in an infant a year and a half old. Both eyes were enucleated, and so far there has been no return, a period of one year. In the second case the condition was not diagnosed, as the lens were cataractous and nothing could be seen. Later on there was great pain, and the eye became disorganized and was removed. A year later the child again appeared with the orbit filled with a neoplasm. The condition was then recognized. The growth was thoroughly removed, and the parts cauterized with chloride of zinc. Five months later, just as healing was about completed, indications of cerebral trouble appeared, and in about ten days the child died. At the autopsy a tumor was found occupying the anterior portion of the brain. A second growth was found in the cerebellum on the right side.

DR. R. J. MCKAY, of Wilmington, Del., reported

A CASE OF ORBITAL CELLULITIS.

PROGRESSIVE ASTIGMATISM,

by DR. EDWARD JACKSON, of Philadelphia.

The author reported seventeen cases in which the increase of the astigmatism in hyperopic eyes had made needful a change of the correcting lenses. Such an increase seems to occur in about two per cent. of all cases. It may be due to chronic congestion of the eye from eye-strain, resembling progressive myopia, or to a congenital tendency of the eye to develop thus asymmetrically. The latter mode of origin was pointed to by the blood relationship of several similar cases. Bearing these cases in mind, the surgeon could not promise that the astigmatism of an eye would remain constant, or assume that a colleague had been mistaken, simply because lenses previously ordered by him did not now suit the case.

THREE NOTEWORTHY CASES OF AMETROPIA,

by DR. SAMUEL THEOBALD, Baltimore.

The noteworthy feature in these three cases was the existence in each of so much better near vision than the age and refractive condition of the patient appeared to warrant. In two of them (Case I and

III), it seemed as though the lids were used (as they can be by narrowing the palpebral aperture and altering the corneal curve) to render the retinal images more distinct. In one case (Case II) it was noted that the pupils were exceedingly small. In Case III it is noted that the pupils were not unusually small.

The detailed histories of the three cases were then given:

CASE I. Male, aged fifty, suffering with asthenopia, headache, etc. Had never worn glasses for distant vision, but for near vision he used $+ \frac{1}{2}$'s, with these he read Jaeger No. 1 at eight inches. The ciliary muscle was active. It was found that in the right eye there was H. $\frac{1}{2}$, and in the left, H. $\frac{1}{2}$ with A. $\frac{1}{2}$. With this correction vision, which without glasses was only $\frac{2}{5}$ (?), was brought up to $\frac{2}{2}$.

CASE II. Dr. T., aged fifty-nine, suffered with asthenopia and hyperemia of lids and conjunctiva. The pupils were exceptionally small. For near vision he used $+ \frac{1}{2}$'s reading Jaeger No. 1 with the left eye, and Jaeger No. 2 with right eye. He was found to have in the right eye H. $\frac{1}{2}$ (V. = $\frac{2}{2} +$), and in the left H. $\frac{1}{2}$ (V. = $\frac{2}{2} -$). For near vision the best results were obtained with $+ \frac{1}{2}$'s for right eye, and $+ \frac{1}{2}$'s for left eye.

CASE III. Mrs. R., aged fifty-four, never wore glasses, but had been able to read the small type of a newspaper. Her manifest error of refraction as corrected was right eye + 6 D. cyl. ax. 70° , left eye + 4.25 D. cyl. ax. 110° , and in near vision the addition of 1.50 D. spher. to these cylinders gave the most satisfactory effect.

AN ANALYSIS OF THE OCULAR SYMPTOMS FOUND IN THE THIRD STAGE OF GENERAL PARALYSIS OF THE INSANE,

by DR. CHARLES A. OLIVER, of Philadelphia.

In an analysis of some of the ocular symptoms in this disease, the author, after making thirty-three special observations of the motor, sensory and purely local conditions, arrives at the following summary and conclusions:

(1) The oculo-motor symptoms of the third stage of general paralysis of the insane which consist in varying though marked degrees of loss and enfeeblement of iris response to light-stimulus, accommodative effort and converging power; lessening of ciliary muscle, tone and action; weakening and inefficiency of the extra-ocular muscle motion, all show paretic and palsitic disturbances connected with the oculo-motor apparatus itself, all of greater amount and of more serious consequences than those seen in the same apparatus during the second stage of the disease.

(2) The sensory changes of the third stage of general paralysis of the insane which, though similar to those found in the second stage of the disorder, are so pronounced as to show a semi-atrophic condition of the optic nerve head and a marked reduction in amount of both optic nerve and retinal circulations, with consequent lowering of centric and eccentric vision for both form and color, all indicate a degenerate condition of the sensory portion of the ocular apparatus with impairment of sensory nerve action.

(3) The peculiar local changes seen in these cases, which consist in conditions of the choroid and retina indicative of more pronounced local disturbance and irritation of these tunics than those found in the second stage of the disease, all represent the result of greater

wear and tear given to a more delicate and more greatly weakened organ.

(4) Both the motor symptoms and the sensory changes, as thus described, in the advanced or third stage of general paralysis of the insane furnish, not only evidence of local disturbance of a more pronounced type than those found in the second stage of the disorder, but plainly show themselves as one of the many peripheral expressions of fast approaching degeneration and dissolution of nerve elements, most probably connected with related cortex disintegration and death.

DR. JOHN GREEN, of St. Louis, read a paper entitled

AN ELEMENTARY DISCUSSION OF SOME CASES OF TIPIED SPECTACLE GLASSES.

A NEW OPERATION FOR SYMBLEPHARON

was described by DR. GEORGE C. HARLAN, Philadelphia.

In this case the lower portion of the lid was adherent to the eye-ball, as the result of the inflammation following an injury from molten metal. The lid was first dissected from the eye-ball, and the skin cut through, except at the attachment at each end. A flap of skin of sufficient size was then dissected below and turned up so that the fresh surface was applied to the lid and the skin surface took the place of the conjunctiva. The result had been very satisfactory.

CYST OF THE IRIS FOLLOWING A PENETRATING WOUND AT THE CORNEAL MARGIN WHICH CAUSED SYMPATHETIC NEURO-RETINITIS,

by DRs. S. D. RISLEY and B. ALEX. RANDALL, of Philadelphia.

A boy of ten was struck, on December 12, 1882, by an air-gun dart in the left eye, which penetrated to the lens, and its withdrawal was followed by prolapse of the iris. This being irreducible, was drawn out and excised, and healing resulted with a slightly cicatroid scar. The right eye had been weak and watery, and on January 22d showed distinct neuro-retinitis, and the vision quickly fell from $\frac{2}{2}$ to $\frac{2}{5}$. Under alteratives and atropine he improved until with $+ 2$ vision equalled $\frac{2}{2} +$ on March 17th, and $\frac{2}{2}$ on April 18th. Two months later there was a sudden attack of blindness with an epileptoid seizure. A year later vision with the right eye was $\frac{2}{2}$, and with the left fingers at two feet. In March, 1890, he returned with the left eye red and watery, and with a cyst of the lower part of the iris. Vision nil. Tension slightly diminished. Enucleation was advised. After a delay of two months, during which time the cyst increased in size and vision declined in the right, the eye was enucleated. The microscopic examination has not yet been completed, but there is no sarcoma in the vitreous chamber.

THROMBOSIS OF THE ARTERIA CENTRALIS; CENTRAL VISION UNAFFECTED,

by DR. O. F. WADSWORTH, Boston.

A young woman, aged twenty-four years, had sudden diminution of vision in the left eye. The field was much contracted, but central vision was unaffected. Examination showed plugging of the central artery. The circulation on the macular region was, however, maintained by an anomalous vessel, a retino-ciliary artery.

DR. F. M. WILSON, of Bridgeport, Conn., presented

THREE SPECIMENS OF FILARI OCULI HUMANI.

DR. GEORGE C. HARLAN reported

A CASE OF TEMPORARY PULSATION OF THE RETINAL ARTERIES FOLLOWING THE APPLICATION OF HOMATROPINE.

DR. HARLAN also exhibited

A MODIFICATION OF THE NOTES OPHTHALMOSCOPE.

DR. B. ALEX. RANDALL moved that the Society express its approval of the method of nomenclature of prisms suggested by Dr. W. S. Dennett. This was adopted.

The following officers were elected: President, Dr. Hasket Derby, Boston; Vice-President, Dr. G. C. Harlan, Philadelphia; Secretary and Treasurer, Dr. S. B. St. John, Hartford, Conn.; Corresponding Secretary, Dr. J. S. Prout, Brooklyn.

The following were elected to membership: Dr. A. E. Ewing, St. Louis, Mo.; Dr. Neil J. Hepburn, New York; Dr. Chas. M. Culver, Albany, N. Y.; Dr. Richmond Lennox, Brooklyn; Dr. Frank W. Ring, New York.

The Society then adjourned to meet with the Congress of American Physicians and Surgeons September, 1891.

Recent Literature.

Diseases of Women and Abdominal Surgery. By LAWSON TAIT, F.R.C.S., etc. Vol. I. Philadelphia: Lea Brothers & Co. 1889.

Lawson Tait's writings, whatever may be thought of their medical value, are at least interesting, and the appearance of this, the most extended treatise which he has published, has been awaited with lively anticipation. It is impossible to read any of the author's writings without feeling at the same time pleasure and disappointment: pleasure at the bold, original way in which he treats his subject, and disappointment at the dogmatic way in which he states his views and the rude manner in which he treats those who differ from him.

The present work is no exception to this statement. While by far the most original, in the sense of the most personal work on gynecology with which we are acquainted, it is at the same time marred by the blemish we have spoken of. Opinions on very doubtful points are expressed with a dogmatism, and a contempt for the views of others, which are, to say the least, exasperating.

On examining into the contents of this first volume we find a great deal which is familiar from former publications of the author. His views on the nature of menstruation, his treatise on ectopic gestation, and his book on "Diseases of the Ovaries," are familiar to the profession, and are wholly or in part incorporated in this book. His division of the subject is based on the organs concerned, beginning with the mons veneris, and then considering in turn the vulva, vagina, urethra, bladder, uterus, ligaments, tubes, and ovaries, in this volume, with a promise of diseases of the pelvic bones, liver and gall-bladder, kidneys, spleen, and pan-

creas, colon, rectum, cæcum, and small intestine, and lastly the breast, to be treated of in the next.

It is impossible in the limits of a short review to consider these various subjects in detail. It will suffice to indicate a few of the more important criticisms which have suggested themselves on a careful reading of the book.

As a direct consequence probably of the fact that this work is, as he says in the preface, "the results of his own experiences," there is observable all through a lack of perspective. Certain important subjects are treated of very cursorily, while others, of no greater importance, receive a great deal of attention. Thus, cancer of the uterus has barely five pages given to it, while ectopic pregnancy and pelvic hematocoele are given one hundred. The explanation of this is that Tait does not believe in operating for cancer, on the grounds that the primary mortality must be heavy; that the few cases in which the disease does not return are clearly errors of diagnosis; and that he likes his work to be stable (p. 117). This looks a little like choosing his operations for the sake of the record.

So, too, uterine displacements are passed over with only scanty mention, while the theory of menstruation is treated of at great length.

We are glad to see the diseases of the external genitalia so fully considered. They are, as a rule, unimportant as regards danger to life, but often very important as regards comfort and marital happiness.

His methods of examination are essentially English, and it certainly seems as if no amount of practice could make a bimanual examination with the patient on the side as thorough or as comfortable to the patient as on the back.

He recommends the flap-splitting operation for vesico-vaginal fistula, a form of operation which would seem well adapted for some cases.

Trachelorraphy he scoffs at, and says that "nothing more useless than Emmet's operation has ever been introduced into surgical practice."

His method of dilating the uterus for relief of stricture, straightening the canal in cases of flexion, and for induction of premature labor by continuous elastic pressure for from twenty-four to thirty-six hours with graduated plugs, is no improvement on the rapid dilatation under ether.

A very interesting and valuable feature is the introduction of numerous detailed cases throughout the book. These are graphically told, and serve to emphasize the points of diagnosis and treatment.

As a whole, the book is so suggestive, original, and picturesquely written, that it will well repay perusal, and it will appeal to a larger circle of readers in the profession than the gynecologists alone: surgeons and general practitioners will find much that is interesting and profitable in it, especially as the second volume promises to deal in part with organs which do not belong to women alone. Its appearance will be awaited with interest.

The Anatomy of the Central Nervous Organs in Health and Disease. By DR. H. OBERSTEINER, Prof. (ext.) at the University of Vienna. Translated, with Annotations and Additions, by ALEX. HILL, M.A., M.D., F.R.C.S. With 198 Illustrations. Philadelphia: P. Blakiston, Son & Co. 1890.

We are much indebted to Dr. Hill for translating this work, which is of great value to specialists in diseases

of the central nervous system, and to advanced students of its anatomy. The book is a very comprehensive one, but, owing to the good judgment of the author in not giving too much space to details and in avoiding the discussion of vexed questions, it is not very large. Yet it contains not only an account of the architecture of the brain and cord, but a section on methods, and something about diseases of the central nervous system. The discussion of the minute structure of the elements themselves and of the putting together of the finer parts is preceded by a section on morphology, in which the gross appearances are described. Many would probably like a fuller discussion of the convolutions, though we think they would admit that it was well to observe brevity. We are not able to see the force of the distinction which is drawn between variations and anomalies. According to Obersteiner it is not an anomaly for the fissure of Rolando to open into the fissure of Sylvius, but it perhaps is one for it to be interrupted by the uncommon development of a gyrus which is usually present but out of sight. Why one of these conditions is more of an anomaly than the other we fail to see, even if we admit what the author seems to imply, that anomalies, properly speaking, verge on teratological conditions.

The general diagrammatic description of the central nervous system is very satisfactory. The illustrations are good, though perhaps hardly as numerous as could be wished. There is a very good series of representations of sections through the medulla and pons, the position of each of which is marked on a diagram.

The translator, Dr. Hill, has not only turned the work into clear English (although we found a new verb,—to myelinate), but has added several annotations. The ones which please us particularly are those in which the subject is elucidated by references to comparative anatomy; as, for instance, the discussion of the relation of the development of the temporal lobe to the sense of smell in different animals. It happens once or twice that the author and translator do not agree, and in such cases it seems to us that the presentation of discordant views is rather confusing than profitable. Dr. Hill adds a chapter in support of his theory of the rotation of the mammalian brain during its development, which is very plausible, to say the least.

There is a good index. The book is of convenient size, and well printed. T. D.

The Treatment of Internal Derangements of the Knee-Joints by Operation. By HERBERT W. ALLINGHAM, F.R.C.P., Surgeon to the Great Northern Hospital, etc. Cloth. Pages 165. Illustrated. London: J. & A. Churchill. 1889.

The object of the writer has been to call attention to certain affections of the knee, which are little understood, or seldom recognized, and to demonstrate that this articulation may be opened with little danger of serious results in the treatment of these conditions. The "derangements" considered are briefly: displacements of the semilunar cartilages; displacements, injuries or pathological changes in the alar ligaments; mures articulorum. The book is a neatly published, clearly printed volume in which the conditions above enumerated are very fully and accurately described. The work of Mr. Allingham at once attracts attention as being entirely new and original. He has carefully studied a common but obscure class of cases; and his

results seem to furnish a satisfactory means of permanent relief to the unfortunate victims of these lesions, the exact character of which has been so little understood. The monograph is valuable and practical, is well written, and is a work which the physician as well as the surgeon should not fail to read carefully.

A Manual of Instruction in the Principles of Prompt Aid to the Injured, Designed for Military and Civil Use. By ALVAN H. DOTY, M.D., Major and Surgeon, Ninth Regiment, N. G. S. N. Y.; Attending Surgeon to Bellevue Hospital Dispensary, N. Y. Cloth. Pages 224. Illustrated. New York: D. Appleton & Co. 1889.

The aim of the writer has been to produce a book which should be what its title indicates, a manual for the treatment of emergencies especially adapted to the work of ambulance corps. The first sixty-seven pages, devoted to anatomy and physiology, are of little practical value, except perhaps some of the outline cuts of the bones. There are few emergencies where it is necessary to know that "the spleen is a ductless gland weighing eight ounces," etc., and that "its function has not been definitely settled"; or that there "are three kinds of sweet breads." The remainder of the book treats more strictly of the subjects indicated in its title, and while principally a compilation is well written. It, however, presents nothing either in its contents or arrangement which will make this volume superior to a number of excellent manuals already in the hands of the profession and public.

A Manual of Minor Surgery and Bandaging for the Use of House-Surgeons, Dressers and Junior Practitioners. By CHRISTOPHER HEATH, F.R.C.S., Surgeon to University College Hospital, etc. Ninth edition. Cloth. Pages 361. Philadelphia: P. Blakiston, Son & Co. 1889.

This book, since the publication of its first edition in 1861, has become so widely known that a description of its character and arrangement is unnecessary. The present edition is equally satisfactory. Compact in form, neat in appearance, concisely written, systematic, practical and convenient in its arrangement, all essential elements of an ideal manual, are still the characteristic of this well-known work. That it has reached its ninth edition and outlived a score of rival treatises is the best indication of its worth. The present volume is somewhat enlarged, but by minor additions only scattered throughout the work without altering its former arrangement. The part of the book which, if any, is open to criticism is that relating to especial treatment. In many instances the methods described are distinctly English; in all cases good, but not always the most modern and efficient.

Massage Kort Framställning. AF DOUGLAS GRAHAM, M.D., M.M.S.S. Bemyndigad Ofversättning af NILS POSSE, Sjukgymnast, etc. Small 8vo, pp. 119. Lund: C. W. K. Gleerups Förlag.

Although we owe to Sweden the movement cure and Swedish gymnastics, little has been done in that country in the way of massage. Baron Nils Posse has, therefore, translated Dr. Graham's excellent essay in "Wood's Handbook." Of the literary merits of this translation we are hardly competent to judge; but we can felicitate the medical profession in Sweden in having this essay rendered accessible to them; and we can also congratulate Dr. Graham that his work has attained the honor of a translation. P. C. K.

Injuries and Diseases of Nerves, and their Surgical Treatment. By ANTHONY A. BOWLBY, F.R.C.S. Surgical Registrar and Demonstrator of Practical Surgery and Surgical Pathology at St. Bartholomew's Hospital. Cloth, pages 510. Four colored plates and twenty illustrations. Philadelphia: P. Blakiston, Son & Co. 1890.

The work is the result of nine years' observation and experience, and is practically a condensation of the Astley Cooper Prize Essay of 1886, with what further knowledge of his subject the writer has derived from three years' additional experience. The data have been collected from clinical observation of large numbers of patients during a long series of years. The introductory chapters treat of the anatomy and physiology of nerves; the changes following their section; degeneration; repair; union by first intention; trophic changes resulting from nerve injury, and the symptoms accompanying such injuries; injuries to special nerves. The subject of nerve sutures is next extensively discussed, and an immediate attempt advised, since in untreated cases a majority result either in non-union or an incomplete one. The subject of secondary suture is also fully considered. The abstracts of fifty cases of nerve suture enable the reader to examine for himself some of the author's reasons for his conclusions. The following chapters discuss the various forms of nerve injuries, namely: contusions; injuries accompanying fractures and dislocations; reflex paralysis; unusual complications, such as epilepsy, chorea or tetanus. The subject is treated at length, and consists chiefly of the abridged clinical histories of especial cases. It contains much valuable data. The remaining portion of the work treats successively of the general treatment of the various abnormal conditions accompanying nerve injuries: neurotomy; neurectomy; nerve stretching, with a discussion of its clinical application; the surgical treatment of neuralgia; non-traumatic neuritis; multiple neuritis; neurroma.

The book is a practical, well-written one, and is especially valuable for the clinical data it contains.

A Treatise on Neuralgia. By E. P. HURD, M.D., Member of the Massachusetts Medical Society, of the Climatological Society, etc.; one of the physicians to the Anna Jaques Hospital, Newburyport, Mass. Detroit, Mich.: George S. Davis. 1890.

This volume of one hundred and fifty pages is published in the paper-covered form which the publishers have made familiar in their series of the "Physician's Leisure Library." Its opening chapter treats of the symptoms and pathogeny of nerve pain; the second classifies the neuralgias, following the scheme of Vauclair. Later ones treat, in more detail, of reflex, toxic and other varieties of the disease; and one chapter is devoted to visceral neuralgias. The concluding chapter, on treatment, is supplemented by a copious appendix, which discusses intelligently and suggestively the large number of remedies, including the newer analgesics, which have been prepared for the relief of the condition, but which, from its length and the wideness of its range, illustrates most vividly the often exceedingly obstinate character of the affection. The volume is dedicated to M. Dujardin-Beaumetz. We can recommend it to the medical practitioner as covering very fairly what is known of the nature and treatment of this most common and distressing affection.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 14, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE GRAND ARMY MEETING.

BOSTON has just witnessed a memorable sight in the annual gathering of the veterans of the late war. It was an inspiring sight to watch the long lines of men who once wore the army blue. None of the old formations were represented in the line of march, but the formations were based entirely on locality, but still one could find something of the old spirit. If the troops from one State gained a reputation for soldierly bearing and effectiveness, the same spirit could be seen to animate the survivors. But a medical man looks with great curiosity upon the physical traits of this body of men, the majority of whom have already passed the age of active military duty, and the remainder of whom at least border closely upon it. Empty sleeves were frequent, and unsteadiness of gait often betrayed some defect in the lower extremities, but as a body, they seemed in the main a sturdy and well-preserved set of men.

Boston may well be proud of one feature of the day, and that was the ambulance service. Emergency stations were established at frequent intervals along the line of march, ready to render aid to such veterans or others as might need assistance. At each station was placed a man with the red cross insignia, who could give needed aid or summon an ambulance. An emergency hospital was established, where beds, food, nurses and medical relief were ready. The ambulance corps of the two militia brigades volunteered their services for work at the red cross stations, while trained nurses, male and female, were equally ready with an able corps of doctors for any duty that the day or the week might call for. Fortunately the day was cool and cloudy, and the actual number of men who required assistance was comparatively small, though over thirty men were transported to the emergency hospital during the time of the march. These men were most of them of a class who ought never to have turned out. Enfeebled by disease or prostrated temporarily by some digestive disturbance incident to the journey, to the meeting, and irregular diet, they succumbed to the exertion of the march, or rather to

the long standing in line and tedious waiting which seem inevitable in a grand procession.

The veterans ought to feel that if occasional criticisms are made on certain acts of their associations, when it comes to personal care for any unfortunate member the same sympathy exists that was shown during the war, and from present indications is not likely to decrease in the rising generation.

THE RECOGNITION OF EYE-STRAIN BY THE GENERAL PRACTITIONER.

OPHTHALMOLOGISTS have been for some time desirous to secure a more general recognition of eye-strain on the part of the mass of practitioners; but ophthalmology has been so much a *terra incognita* to the average physician, that the subject has been only too generally passed by as a field requiring unusual ability to use the refraction ophthalmoscope, shadow test, etc.

Dr. Edward Jackson has lately read a paper before the county medical society in Philadelphia, in which he very justly says, that, if the general practitioner would search for the symptoms, he could make a probable diagnosis, with fair assurance of success. That this is a fact cannot be doubted, for the condition is well enough marked to be often recognized by the patient himself, without the aid of a medical man. The chief obstacle to the recognition of eye-strain is the fact, that, either the eyes are not considered at all in making up the diagnosis, or preconceived hypotheses as to the causes of the symptoms tend to divert attention from the real cause.

The symptoms in question are often very characteristic, and easily gotten at by ordinary questioning. The first symptom is likely to be temporary impairment of vision, due to a sudden relaxation of the accommodation, when the ciliary muscle has been long overtaxed. The patient notices that print upon which the attention is fixed becomes entirely blurred, but that if he closes his eyes for a moment, or perhaps rubs them, he can read again. The next prominent symptom is headache, which is so commonly associated with eye-strain that it should immediately suggest its presence. In fact, eye-strain enters as a factor into the causation of nearly all headaches not due to pyrexia, toxæmia, or diseases of the brain or its membranes. It often comes on when the eyes are used, and is absent at other times. Headaches in school-children are almost always due to eye-strain; and the headaches of adults which follow travelling, shopping, sight-seeing, or attendance at the church or theatre, are due to eye-strain, although commonly believed by the patients to be due to fatigue, bad air of the auditorium, excitement, and so on. In these cases the location of the headache has some significance. It is generally described as beginning just over the eye, back of it, or through the temples, frequently extending to the occipital region, and sometimes is wholly confined to the occiput. Pain in the vertex is almost never due to eye-strain.

Such cases are often accompanied by chronic inflammation of the margins of the lids, or of recurring conjunctivitis, and repeated stys; such conditions being attributed to repeated colds. It is true in this, as in other morbid conditions, that one or the other of this group of symptoms may be absent; nevertheless, the clinical picture is sufficiently distinct, so that any practitioner should be able to diagnosticate a probable cause without recourse to specially-devised instruments of precision.

MEDICAL NOTES.

— The Berlin International Medical Congress is busily at work. Among the Americans who have read papers are: Dr. V. Y. Bowditch, Boston, on "Galton's Law of Growth"; Dr. Loomis, New York, on Consumption in Hospitals"; Dr. Jacobi, New York, on "Diphtheria in America"; Dr. Marcy, Boston, on "Hernia"; Dr. F. H. Watson, Boston, on "Removal of Intra-Vesical Growth"; Dr. Bradford, Boston, on "Club Foot."

— Dr. Edward C. Passmore, an old New York practitioner, died August 1st. He was born in Dublin, Ireland, in 1813. He was graduated from the Dublin College of Physicians, and was a licentiate of the Dublin College of Surgeons. He came to this country in 1836, soon after graduating, and settled in New York, where he built up a large family practice in the then fashionable district in the vicinity of East Broadway. About 1860 he moved up to Thirty-Fourth Street, and for many years he was a sanitary inspector of the Board of Health; it being only three years ago since he retired from the service of the department. In 1839 he was married, and on June 21st of last year, celebrated his golden wedding. Mrs. Passmore died in February of this year, and only one child, a daughter, survives him. One of his sons, a young physician of promise, died of typhus fever while in the medical service during the late war.

Miscellany.

POSTHUMOUS LABOR.

THE following certainly remarkable case is related in the *Lancet* for July 19, 1890:

"At Moglia, in the province of Mantua, occurred a case of post-mortem delivery in some respects unique. A woman, Lavina Merli by name, subject to chronic epilepsy, had suddenly lapsed into the cataleptic state when in the eighth month of pregnancy. So death-like was the trance that she was certified as dead and ordered to be buried. The coffin containing the unfortunate woman was closed and deposited in the mortuary chapel pending the gravedigger's work, when next morning it was found with the lid raised. The woman's body — now a corpse — was horribly contracted, and, closely pressed between the knees, lay a new-born child, quite dead. The gravedigger and his men, for reasons of their own, kept their discovery a secret and buried the two corpses. The facts, however, leaked out, and the judicial authorities, aided by phy-

sicians from Mantua, at once proceeded to exhume the coffin and examine its contents. A very minute and prolonged inspection was made, with the result that the physicians declared themselves satisfied that the mother was already dead when the child was expelled from the womb. From the position of the bodies and the commencing decomposition in which they were found, taken in connection with other considerations set out at length in the official report, the conclusion was arrived at that the gases, disengaged by the putrefactive process, and seeking an exit, had forced out the fetus; that, in short, the case was one undoubtedly very rare, but by no means unprecedented, in obstetric experience of 'posthumous labor.' The incident, however, has attracted notice beyond the Mantuan province, and medico-legal discussions on its details is yet far from being exhausted. It is asked, not unnaturally, if the woman Merli had really ceased to live, how the coffin-lid came to be even partially raised? She is not by any means the only patient, in catalepsy or 'nona,' who, in quite recent Italian experience, has been certified as dead and treated accordingly; and the anti-cremationists, making the most of such cases, are warning the public how still more slender, in 'apparent death,' would be the chances of escape for Merli and her like, if, instead of the coffin, she had been consigned to the crematorium."

NINETY CASES OF DYSMENORRHEA AND STERILITY TREATED BY RAPID DILATATION OF THE CERVICAL CANAL.

THE following are the figures given by Dr. Townsend in the *Albany Medical Annals* as the result of his experience in the practice of rapid dilatation under complete anaesthesia with rigid antiseptic precautions: Dilatation in virgins for dysmenorrhœa, other means failing, 57; complete cure of dysmenorrhœa, 53; no better, 3; made worse, 1.

Dilatation in married women for dysmenorrhœa and sterility, other means failing, 33; complete cure of dysmenorrhœa, 33; complete cure of sterility, 27; remaining sterile two years or more after operation, 6.

HOW DIPHTHERIA IS SPREAD BY CORPSES.

DR. C. W. CHANCELLOR in a letter to the *Baltimore Sun*, thus graphically sets forth the mischief that may follow the concealment of cases of diphtheria and the permission of public funerals in such cases.

"About the middle of last June a grandchild of Mr. Arthur Thomas of Prospect, Harford County, Md., died in Wilmington, Del., of throat disease. The attending physician, it is stated, refused to give a certificate upon which the body could be removed, but another physician was found who certified that the child died from 'lung trouble,' and upon this the body was received and transported on the 17th of June by the railroad company into this State. Mr. Thomas and his daughter, aged eighteen years, attended the corpse. On June the 18th, after arriving at home, the coffin, an ordinary casket, was opened and the remains viewed by the family, who were thus exposed to the contagion of the disease. Two days after, the daughter who, with her father, had accompanied the corpse from Wilmington to Prospect, was taken sick with diphtheria and died on the 23d of the month. The same day,

namely, the 23d of June, another daughter, aged eleven years, came down with the disease and died on the 30th of the month. In the meantime a third daughter sickened and died on the 6th of July. On the 5th of July, the son, Robert, was taken sick and died three days after with malignant diphtheria. This is quite similar to an occurrence which took place at Zanesville, Ohio, last spring, where many deaths resulted from exposure to a corpse brought from Chicago, and to another where a child died March, 1890, in Montgomery County, Michigan, of diphtheria, was certified by attending physicians to be 'not dangerous to the public health,' and was conveyed to Lapeer County, Michigan, where just one week from the day the coffin was opened and the remains viewed a person who was exposed died from the disease, and many others would probably have been exposed except for the action of the local or county health officer, who warned the neighbors of the danger, and ordered the coffin to be closed and the corpse buried. Such cases show the importance of notice being given promptly to the health authorities of all deaths from contagious or infectious diseases, so that every necessary precaution may be taken to prevent the spread of such diseases. They also emphasize the crime of any misrepresentation being made in a death certificate, and of railroad companies transporting bodies dead of a malignant or dangerous disease."

SOME NEW ADVICE TO THOSE WHO WOULD PRACTICE ANTISEPTIC MIDWIFERY.

A WRITER in the *Journal de Médecine de Paris* humorously "takes off" the practice of some of his contemporaries who would carry antiseptic obstetrics to excess. Under the head of "Counsels of Lucina" (Lucina was the goddess of childbirth), he gives some rather extravagant advice to young practitioners:

"The antisepsis must be complete and absolute, or it is a delusion.

"On rising in the morning, take a full bath of soap and water; the scrubbing should be done in earnest.

"The hairy scalp cannot be too thoroughly clipped or epilated every month, for it has been demonstrated that the hair furnish shelter to quantities of microbes; the same precautions are necessary for the beard and other hairy regions of the body.

"The eye-brows and eyelashes being indispensable to the hygiene of the eyes, should be respected, but they should be well scrubbed every morning with Van Swieten's solution.

"The nasal cavities should be carefully swabbed out; it would even be prudent to stuff them during the day with iodoform gauze; as respiration can go on quite well by the mouth.

"The ears should be carefully douched by a specialist knowing well the direction of the external auditory passage, and it would be well by a Eustachian double-current catheter to wash out the middle ear. The mouth being a cavity frightfully septic, the prudent practitioner will divest it of all useless ornaments. The natural teeth being receptacles and lurking-places of numerous microbes, should be extracted and replaced by artificial teeth, which the physician will wear as little as possible, and only to eat with, or when he goes into society; at other times these little masticatory apparatuses will be kept soaking in a strong carbolic solution.

"It will also be advisable to make every morning a serious laverment of the stomach and rectum, for these cavities breed bacteria, and there is a possibility even of communicating infection by the gases eructated from the stomach.

"The carriage in which the physician visits his patients should every morning be washed inside and out in a full stream of antiseptic water, and the wheels should be well greased with carbolized oil. It will be well to keep the inside of the carriage aseptic by means of a suitable spray-producer which may be made to work automatically in some part of the vehicle.

"The carriage-box should be replaced by a dry stove, which should be always in operation. Whenever the physician has occasion to visit one of his lying-in patients, he shall change his clothes and place those that he has taken off in the stove in question. The same garment should never be worn in the sick-room of two consecutive patients without being disinfected.

"Whenever the physician enters a patient's house, he will have care to demand immediately a pair of slippers, which he will put off on leaving the house; otherwise his boots will become impregnated with a prodigious quantity of microbes. He will also take pains not to shake hands with any one, else he might be infected by the simple fact of contact.

"Whenever a patient has died of any affection sup-

posed to be microbial, the physician will abstain from all medical visits for at least a week, and he cannot do better than pass this time at the top of the tower Eiffel, where no microbes are supposed to live.

"From time to time the physician may dine in town, but he will be served apart on a little table, so as not to be infected by contact with neighbors; and he will take care to eat with his fingers, for the usage of the disinfecting stove has not yet entered into the hygiene of the kitchen, and the knives, forks and spoons may be covered with micro-organisms. He may, however, bring with him his dishes and other implements for eating previously disinfected. He will scrupulously abstain from all food that has not been thoroughly boiled, and for drinks, religiously refrain from everything less aseptic than distilled liquors."

There is much more of the same sort of advice in the article alluded to, but we have given enough to indicate to our readers in what direction the sceptics think antiseptic midwifery is tending.

Microphobia has occasioned a revolt among the surgeons, and we see such excellent teachers, as Professor Leon Le Fort and Armand Després, declare themselves still partisans of the older methods. The latter, in his *Chirurgie Journalière*, under the head of "Surgical Dressings," describes the Listerian method of treating wounds, only to add: "All these minutiae seem to me tedious and puerile; but one thing more is necessary to add, namely, some exorcisms."

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 2, 1890.

Deaths reported 3,556; under five years of age 1,841: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 1,218; consumption 302, lung diseases 168, diarrhoeal diseases 887, diphtheria and croup 110, typhoid fever 87, whooping-cough 54, malarial fever 25, measles 17, cerebro-spinal meningitis 16, scarlet fever 16, pulmonary fever 4, erysipelas 3.

From whooping-cough, New York 15, Philadelphia and Brooklyn 11 each, Chicago 8, Baltimore, Lowell and Cambridge 2 each, Boston, Nashville and Salera 1 each. From malarial fevers, New Orleans 10, Baltimore 6, New York 3, Philadelphia, Brooklyn and Charleston 2 each. From measles, New York 14, Brooklyn, Boston and Lawrence, 1 each. From cerebro-spinal meningitis, New York 7, Chicago 5, Philadelphia 2, Brooklyn and Cambridge 1 each. From scarlet fever, New York, Chicago

and Brooklyn 4 each, Philadelphia and Chelsea 1 each. From periperal fever, Chicago 3, Philadelphia, 1. From erysipelas, New York, Chicago and Washington 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending July 18th, the death-rate was 18.0: deaths reported 3,351: acute diseases of the respiratory organs (London) 216, diarrhoea 172, measles 159, scarlet fever 55, whooping-cough 86, diphtheria 31, fever 23.

The death-rates ranged from 11.9 in Derby to 26.2 in Manchester: Birmingham 16.9, Brighton 15.2, Hull 12.4, Leeds 21.6, Leicester 19.6, Liverpool 19.4, London 17.9, Newcastle-on-Tyne 21.8, Nottingham 15.6, Sheffield 21.5, Sunderland, 18.0.

In Edinburgh 16.7, Glasgow 18.9, Dublin 20.7.

The meteorological record for the week ending Aug. 2, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps: -

Week ending	Barom- eter.	Thermometer.	Relative Humidity.	Direction of Wind.	Velocity of Wind.	State of Weather.*	Rainfall.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 9, 1890.

WALES, F. S., medical director, ordered in charge of the Museum of Hygiene, Washington, D. C.

BRIGHT, GEORGE A., surgeon, ordered to the U. S. S. "Constitution."

MACKIE, B. S., surgeon, detached from the U. S. S. "Constellation," and to Naval Hospital, Philadelphia, for medical treatment.

DEER, E. Z., surgeon, ordered to the U. S. S. "Minnesota."

WAGGON, J. R., surgeon, detached from the U. S. S. "Minnesota," and ordered to the U. S. S. "Kearsarge."

MOORE, A. M., surgeon, detached from the U. S. S. "Kearsarge," and granted three months' sick leave.

SOCIETY NOTICE.

AMERICAN DERMATOLOGICAL ASSOCIATION. — The Fourteenth Annual Meeting will be held at Richfield Springs, New York, September 2, 3 and 4, 1890.

The following papers will be read:

First Day. — Morning session at 10.30 A. M. Address by the President, Dr. P. A. Morrow. Observations on Prurigo, Clinical and Pathological, Dr. R. W. Taylor. Prurigo in the Negro, Dr. R. E. Morrison. A Clinical Study of Pruritus Hiemalis — Winter Itch, Frost Itch, etc., Dr. W. T. Corlett. Study on Pruritus, Dr. E. B. Bronson. Afternoon session at 3.30 P. M. Note: Read, two cases, probably "Cancer en Crustae," Dr. J. S. Hyatt. A Case of Arthropathic Mucous of Striata following Typhoid Fever, Dr. F. J. Sheppard. Electrolysis in the Treatment of Lupus Vulgaris, Dr. G. T. Jackson.

Second Day. — Wednesday, September 3, 1890. Immigrant Dermatoses, Dr. J. C. White. Notes on some Rare Cases, Dr. G. H. Fox. Cases of Cutaneous Tuberculosis, with Histological Studies, Dr. J. T. Bowen. Cases from the Hopkins Hospital Clinics, Dr. R. B. Morrison, Plica, Dr. H. W. Stelwagon. Treatment of Erysipelas, Dr. C. W. Allen.

Third Day. — Thursday, September 4, 1890. Remarks on the Treatment of Dermatitis Herpetiformis, Dr. L. A. Duhring. Treatment of Ringworm and Favus of the Scalp, Dr. H. W. Stelwagon. Note on Phimosis in Dermatology, Dr. H. G. Kutz. Report of a Friend, Dr. C. W. Allen.

Retirement of old and induction of newly elected officers. Adjournment.

OBITUARY. JOHN NELSON BORLAND, M.D.

Dr. Borland, who died at Boston, August 10, 1890, was born in Boston in 1828. Graduating from Yale College, in 1847, he studied medicine in New Haven Street Medical School. Dr. Borland received his medical degree from Harvard University in 1850, and became a house-officer in the Massachusetts General Hospital. He was appointed one of the first visiting physicians of the Boston City Hospital. From 1859 to 1873, he was Instructor of Clinical Medicine in the Medical School of Harvard University. Dr. Borland was well known and greatly beloved in Boston. His cordiality of manner, his fine presence, his genial disposition made him a favorite wherever and in whatever relation his influence was exerted. He was a skillful practitioner, and his social gifts, his gentle sympathy endeared him to his patients, whether rich or poor. He was an active member of Boston medical societies, and a devoted student of his profession. His memory will nowhere be more affectionately recalled than at Nahant, among his old friends and summer visitors he practised in the most serviceable and conscientious manner for a long series of years. Dr. Borland retired from practice in 1878, and since that time has resided at New London, Conn. He died after a long illness, and leaves behind him the example of an honored physician, an upright gentleman and a loyal friend.

SOME ASPECTS OF OUR MEDICAL SERVICE
IN THE WAR OF THE REBELLION.¹

BY GEORGE H. LYMAN, M.D., BOSTON.

BEFORE proceeding, a few words seem necessary as to this newly-created addition to the regular army, of medical inspectors. It was a novelty in the medical service, organized in the hope that it would add very much to its general efficiency. It was a staff corps, assigned to different departments as occasion might require, for longer or shorter periods of inspection, and not reporting to department commanders but to Washington direct. Though not under department control, it should be added that it invariably met with the cordial co-operation and assistance of the generals in command. It was given the increased grade that there might be no longer question of its authority. One-half its members were chosen from recent civil appointments, and one-half from the staff of the regular army, regardless of their previous relative rank. This was a grievance to the old Regulars, to which they could never reconcile themselves.

It seemed impossible for those who had grown old under the former régime of promotion by seniority to realize the changed circumstances, — that this was essentially a war of volunteers, on an unprecedented scale. They could not resist the idea that these additions to the corps from *civil* life were purely political appointments for the attainment of soft places and promotion.² If this was a hardship to a few, it was a necessary incident to the enormous expansion of the army, the exigencies compelling an entire revolution in the conditions required for our small normal peace establishment. They ignored the fact, that, like themselves, we had entered the service after examination by a board of their own number and with our commissions from the President.

Many a senior of the old army, was, as you know, required to serve under some one his junior at West Point, or even under some civilian general in his first uniform. McClellan, Meade, Hooker, Burnside, Warren, St. George Cooke, Franklin, Butler, Banks, Logan, Sheridan, and so on, need only be cited as examples on both sides; and in the medical service, the office of surgeon-general, even, was filled, as we have already seen, at very early period (April, 1862) by a young assistant surgeon of the army promoted at one jump over his seniors, half a dozen of whom were in the service before he was born.³

That all the results hoped for from this corps of inspectors were not fully realized, may be frankly con-

¹ Abstract of a paper read before the Massachusetts Historical Society, May 10, 1864, (reprinted from page 119 of the Journal.)

² I was constantly reminded of this misconception, that I was aiming for the surgeon-general's position, forgetful that, by terms of the law, these appointments ceased with cessation of the war.

³ Since the war various changes have been made in the law regulating promotion. The act of July 28, 1862, directs that heads of departments "shall make it their duty to see that all officers in the corps to which they belong . . . shall be promoted by merit, and the corps gives no claim. The grade of brigadier was established as a new office, for the very purpose of enabling selection of the most competent men, regardless of their previous rank. Hammond, an assistant surgeon, became general brigadier, captain, quartermaster-general; and similar selections followed, soon, or later, in the engineer, commissary and pay departments; while the superseding of their seniors by McClellan, Grant, Sheridan, Meade, McDowell, etc., are familiar to all. To quote from one who has been in some thirty years in the service: "In my rule, the law has been broken short prospectively and extensively; and experience shows that such men have but rarely the zeal or capacity to carry on a high grade of administrative work. Speaking generally, they are too old and have been too long subordinate, to originate it."

ceded. That it accomplished much cannot be disputed: that it did not accomplish more was due less to its members than to other causes, some of which may be found in this paper.

The duties, though fairly defined in a general way by the law, were, in detail, left very much to the interpretation of the surgeon-general, without whose hearty co-operation and support they could easily be rendered nugatory, when treading too hard on old traditions, gouty toes, pet plans, or political influences, which an inspector, even if so disposed, had no time to combat.⁴

The inspectors were required to report monthly upon every hospital in their department; to keep posted on the available supplies in the depots; to investigate reports as to inefficiency of medical officers; to discharge, on proper evidence of disability, those who required it; to examine and recommend proper sites for hospitals; to see that hospital boats and trains were properly managed; to carefully inspect camp police; in a word, to be eyes and ears for the surgeon-general and those in command of armies.⁵ The amount of travel, the labor, and responsibility for accurate reports, involving sometimes the character of subordinates, who, if reprimanded or dismissed, were, with their more or less large circle of influential friends, not slow to make their enmity known and felt, made the position no sinecure. Whether from the increased rank and unusual powers given by the law creating the grade, jealousy of supervision, or interference with jobs, or other reasons, the corps too often appeared, as I have said, to lack the cordial support of the surgeon-general's bureau. It was often easier to get prompt correction of negligence or abuses through personal influence with department commanders, and reporting results only to Washington. An inspector constantly migrating through his large department could not always follow up his own recommendations, and, if not approved, have the opportunity of justifying them. Department directors, with few exceptions, gave only such information as was formally demanded, instead of affording full and frank expositions of affairs, which the inspector was left to hunt up for himself. An inefficient officer would be retained by some secret influence; a new hospital, not needed, or badly located or constructed, would be accepted, regardless of remonstrance. Much, of course, was unavoidable under stress of emergencies, but much could have been avoided and to the great profit of the service.

From Washington, I was ordered to duty in the Western Department, comprising Western Virginia, Ohio, Kentucky, Tennessee, and as far south as our lines would permit. A large number of hospitals were grouped on the Ohio River, at Louisville, Cincinnati, New Albany, Mound City, etc., in hastily extemporized buildings — schoolhouses, churches, warehouses, etc., as became necessary for the crowds of sick and wounded from the front, notably Shiloh.

Many were in excellent order, doing good service; others overcrowded, badly policed and badly served. Their officers, as a rule, did all that could be done; but here, as elsewhere, the best results could neither

⁴ An appeal to the Chairman of the Military Committee, or even to the Senate itself, would have made things rather lively for a while; but it would have been, notwithstanding, less insubordinate and undignified, savoring too much of the methods of hospital bummers and wire-pulling.

⁵ General Order, 308, September 12, 1863. Also, Hammond's instructions to medical inspector.

be attained, nor even expected, until the government realized the necessity and economy of large general hospitals specially designed for the purpose. At the present day, when antiseptic surgery gives such brilliant results, and when the successful physician knows that sanitation and good nursing are better than drugs, it becomes more and more a matter for wonder, that, in the damp, dark, ill-ventilated old buildings, with their impure surroundings of earth, air and water, the mortality was not often infinitely greater. But for the field hospitals under canvas, and free exposure to the air, worse results might have been reasonably anticipated. . . .

An early tour of duty took me to Jackson, Tenn., then under Logan's command; to Columbus, Ky., recently evacuated by the Confederates, leaving behind them little but their tracks and a foul area for our occupation; thence to General Sherman's command at Memphis, where I found, in a large, unfurnished hotel, sheltered some 400 or more wounded. A goodly proportion of these were totally unfit for further service, and were clamorous for discharge. By recent orders department commanders could give them this on the recommendation of an inspector, without delaying for the regulation requirement of sending the papers first to Washington.¹¹ Making up a long list, I returned to headquarters for my first interview with the general, he being out at my first visit. Presenting it, and requesting prompt action in the interests of the men and hospital, he offered to send the papers on at once. Being told that such delay was unnecessary, he intimated rather gruffly his surprise at any one's coming to his department to teach him his duty; but soon discovering by reference to his file of orders that this one had been overlooked, he, with great cordiality invited me to dinner. He was much interested in, and anxious to hear about the Army of the Potomac, where I had been medical director of his old division, under General Porter. He was utterly incredulous as to the possibility expressed of Porter's conviction in the trial then progressing, giving in terms more emphatic than polite his opinion of one of his accusers. . . .

Returning to Nashville, I found the churches and warehouses filled with the wounded from the recent battle of Stone River. Abundant supplies had accumulated since the battle; but through *some one's* negligence, as will be seen, the army left Nashville with its medical department meagrely provided. A part, even, of this scant supply was captured before reaching Stone River, by the driving in of the right wing during the first day's fight.

The pike from Nashville to Murfreesboro' (General Rosecrans's headquarters since the battle of Stone River), some thirty miles long, was infested by guerrillas, necessitating an escort for trains and small parties. My predecessor, Dr. Hamilton, venturing it alone, had been recently "held up" at Lavergne, and robbed of horse, instruments and everything down to his boots.

We met Granger's corps on its way to the rear, after a long tour of duty in the field. Ragged, and quite unlike our Eastern troops, they had, nevertheless, the bearing of veterans. My English companions, who had served through the entire Crimean campaign, and who knew a soldier when they saw him, were enthusi-

astic. "A jolly good lot," "solid fellows," "they mean business," etc., were expressions which betrayed the impression made by their first view of American soldiers.

At Murfreesboro' (January 13, 1864), the medical department was found in a deplorable condition. Complaints came from all sides, not only from our own officers, but from sanitary and other civilians, of the general inefficiency and neglect of the chief medical director. Of the three army corps, one medical director alone (a surgeon of volunteers) had been able to meet his own urgent needs, from supplies which he had had the foresight to secure before leaving Nashville, regardless of regulation limitations.

The chief medical director, an easy-going, good-natured man, relying too much upon his subordinates, had made but little personal inspection into the actual condition of affairs, although ten days had elapsed since the battle. One instance only. During my rounds, I came upon a small regimental tent-hospital, one of its beds occupied by a poor fellow with bad compound fracture of the thigh; no splints, no extension, filthy bedding and general neglect. The surgeon absent, no one knew where. It appeared also that he and his hospital steward messaged together. Such a case of incompetency, or worse, could not be overlooked. This part of the report was returned from Washington to the department, and submitted to a board of medical officers, without any notification to me, or opportunity to justify the charges. They gravely decided that the accused was an "excellent officer," and that "they found no cause for censure." The general commanding the division, as I was informed, was a neighbor and especial friend of his worthy doctor, and enjoyed, no doubt, the opportunity of sending this valuable information to me, after I had left the department, with his approval indorsed.

A crying evil throughout the country was especially apparent in this Department of the Cumberland, to wit: the facility with which surgeon's certificates of disability were granted, enabling the slightly wounded to get home, where, surrounded by family sympathy and comfort, wounds were sure to heal with incredible slowness.

This abuse was not peculiar to our service. The French inspector-general, in his special report from the Crimea, urges the imperative need of putting a check upon this absenteeism, this craving for the family hearth-stone, so natural, but so enervating to the army. He says that of every hundred sent back to Marseilles, *ten only* needed hospital treatment.¹²

General Rosecrans was extremely annoyed and incredulous, on hearing the condition of affairs, defending his medical director, on the ground that transportation had been wanting; but when convinced that his army had left Nashville without any previous report to him of this lack of supplies, that his sick and wounded were, since the battle, suffering from this neglect, and that so many trifling wounds had been allowed to leave his jurisdiction unnecessarily, he promptly gave his co-operation in compelling the needed commissary and other changes, relieved his medical director, and established a large field hospital under canvas. . . .

In Nashville, during the winter of 1862-63, supplies were scanty, wood scarce, shade-trees and groves were necessarily sacrificed, hardly boards enough for coffins

¹¹ General Orders, 53 and 65, May 16, 1862. Also, Act of Congress, May 24, 1862.

¹² Bandens, p. 36.

for the dead, and little coal obtainable, owing to low water in the Cumberland. Under these circumstances, some, even of the most prosperous families, were dependent upon us for daily necessities, but in spite of this, the hostile spirit was not concealed. Some of the ladies (or women) were amusingly eager to show their contempt and fear of contamination by giving a wide berth to officers encountered, though there were many charming well-bred people who, without disloyalty to their friends, had too much dignity and self-respect to exhibit any personal rudeness. A few indeed were as hospitable as their facilities for hospitality would permit. The insolence of the former, however, reached such a degree that the commandant found it necessary to administer a rebuke. One day a convoy of wounded Confederates, with a number of their own surgeons, came in from Murfreesboro'. They were soon surrounded by these female patriots, and with such insulting demonstrations to the North that they were ordered to receive this convoy to their own houses, with a curt intimation, that any lack of proper care would be visited with severity. Making an inspection a few days later, I found these men miserably fed, and neglected by their own surgeons, who seemed perfectly indifferent to their duties.

The poor fellows begged to be sent to our hospitals, and their devoted countrywomen showed no reluctance, having evidently had quite enough of them. The change was soon made, the surgeons being sent over to General Bragg with a report that must have assured for them a sweet reception from that amiable officer. . . .

Comparisons have been often attempted between the Western armies and the Army of the Potomac. It would be presumption in me to offer an opinion. The deeds of the Western men speak eloquently enough for them as soldiers, — but for the medical service, I have the right to assert for them an equality, at least, with that of the Atlantic States. Nor were the exceptions to a high standard more frequent there than here. The more important centres, such as Cincinnati, St. Louis, Louisville, Nashville and Memphis, were as well provided and as skilfully managed as in our larger Eastern cities, and they had the advantage of being far enough from Washington to be, in some respects, independent of red tape. Every surgeon knows that the steel edge is apt to be dulled by too much gold or silver plating.

In March, 1863, was ordered to the Department of the East, comprising New England, New York and Northern New Jersey, with from seventy to eighty hospitals and posts for monthly inspection, including among them some of the largest hospitals in the country, and the large prison-camp of Elmira. The monotony was varied by frequent special investigations, under orders from the Secretary of War, such as a visit to the Department of the South for report as to the sanitary condition of General Sherman's army on its arrival at Savannah; inspection of the medical service in that department; inquiries into alleged abuse of patients at Portsmouth Grove, New Haven, Newark and Fort Adams; choosing sites for new hospitals in reply to demands of State authorities; and like matters.

The visit to Savannah was in December, 1864, and the day after arrival at Hilton Head, the 23d, a dispatch was received that Sherman had arrived, and that the rams in the river were blown up. Communica-

tions were not, however, opened for some days, and this interval was utilized at Deveaux Neck, Beaufort and Morris Island, the latter a graveyard for dead soldiers and decomposing filth.

I was fortunate enough to be in Savannah (December 31, 1864) in time for a lunch given by his staff to General Sherman on New Year's Day (January 1, 1865). As an instance of his proverbially tenacious memory, I would say that the general not only greeted me by name, but at once resumed the subject of our conversation at Memphis fifteen months before, by saying, "You were right after all about Porter"; his mind having in the mean time been bothered with all the cares and anxieties of his campaigns from Memphis to Savannah. Something being said of Charleston, I hinted, so far as I dared, at his probable future movements. After a moment's reflection and with a peculiar smile, he said: "Well, I am going along down the coast, cleaning up things on the way, till I get to Boston, wipe that out, and retire."

Called on the mayor (Dr. Arnold) whom I had known previously. He was sitting over an apology for a fire, no fuel being attainable. His reception was cordial, but the interview was a sad one. The war, he said, had utterly ruined him. Finding that the result was inevitably against them, he had some time before endeavored in vain to get the inhabitants to send in their submission to Sherman, but that now they were glad enough of his arrival to offer them protection against the lawlessness of Wheeler's cavalry, who had been holding "high jinks" to the annoyance and terror of everybody. At the Pulaski House, it was difficult to get the scantiest of meals, and as to fuel, it was a luxury indeed.

Sherman's efficient medical director (since Surgeon-General Moore) had so well managed as to bring many of his wounded with him. Others, it was said, refused to be left, and pluckily stumbled through, who in other circumstances would have dropped by the wayside. Some bad cases even improved with every day's movement, in such transports as could be improvised — which all goes to show the marked difference between success and defeat in their relations to the *morale* and *physique* of the soldier. As promptly as transportation could be provided, they were either transferred by sea to Northern hospitals, or properly provided for before the march North was undertaken. . . .

At Fort Pulaski, 314 Confederate officers were imprisoned. One of them had been in hospital two months. On arrival they were already suffering from diarrhoea, dysentery, scurvy, etc., but for two weeks preceding the inspection, having convalesced in some degree, they had been placed on what was cheerfully called "retaliatory rations." They were all without other clothing than such as they had on when captured — one-third without blankets, and all with insufficient food and no money. By a charitable evasion of the order, the hospital case had been in some degree mitigated. At Hilton Head also, the provost-guard's barracks contained 329 prisoners — 237 of them officers, housed in two barracks 86 × 26 feet, with double bunks, the bedding being only such shavings as they could gather from the open area of the prison enclosure, and no fires allowed in quarters. For three weeks their rations, also, had been "retaliatory" namely, ten ounces of meal, four ounces of bread, eight ounces of pickles and one-fifth of an ounce of

salt.¹⁹ They cooked the meal as they best could in their tin mugs, with such heat as they could get from the damp chips and scraps of fuel at their disposal. They complained bitterly of this treatment. I find the following sentence in my official report: "Police of quarters of rebel officers filthy in the extreme, without fire or bedding, and that of the log-cells of other prisoners beggars description. The ammoniacal odor and the want of suitable light and ventilation rendered it the most disgusting and filthy that it has ever been my lot to see occupied as a prison."

Making this state of affairs the subject of an earnest protest at headquarters, I was told that "it took like wildfire at the North!"

Whatever may have been the barbarities committed at Andersonville — and as the statistics clearly prove they were cruel beyond description — neither our own government, nor the people whom they represented, ever manifested a disposition to starve or maltreat prisoners. The journals of that day contain, here and there, wrathful articles excited by some fresh outrage at Libby or Andersonville; but the great mass of our people were only stimulated by them to a more determined prosecution of the war, not to unworthy retaliation in kind. The *Red Cross* is the banner of the Nineteenth Century. . . .

After a somewhat animated conversation General Foster was finally convinced of the wisdom and necessity of modifying his orders, much to the relief of the chief commissary and others; nor did I rest until assured of the result, by carrying the order myself. . . .

In connection with this subject of prisoners, I may here refer to the large prison-camp at Elmira. It is useless to deny the fact that such unfortunates were not always in clover with us. It must, however, be again asserted, and emphatically, that not only as a rule were they never designedly treated with harshness or cruelty, but that very large numbers of them, sick and wounded, were always to be found in our hospitals, placed in the wards on an equality, in every respect, with our own men, and, with very rare exceptions, always grateful, always on good terms with the other inmates, chaffing each other good-naturedly as "Yanks," or "Rebs," constantly appealing that they might not be sent to their friends over the lines. Unless forewarned one would rarely have recognized them as prisoners. Many a time on demanding the name and regiment of a patient, the reply that he was from Georgia, Alabama, North Carolina, or other of the Confederate States, afforded the first information of his status. . . .

Doubtless there was, for a while, much unavoidable suffering at Elmira. The location of the camp, which was originally established as a recruiting rendezvous on the low, sandy border of the Chemung River, the water percolating the gravel a foot or two from the surface, proved to be injudicious. The small shelter-tents were at times overcrowded, and the occupants, clothed in their butternut rags, were not always free from vermin on their arrival — depressed, disheartened, enfeebled by their experiences, in some instances, as in the case of those from Newbern especially, half of them already on the sick list — could hardly be other than miserable.

¹⁹ In June, 1864, six months previously, the following ration for prisoners in hospital had been established by government: pork or bacon 10 oz. (in lieu of fresh beef), or fresh beef 14 oz.; flour or soft bread 16 oz., or hard bread 14 oz., or corn meal 16 oz. To every one hundred rations: beans or peas 12 lbs., rice or hominy 8 lbs., soap 4 lbs., vinegar 3 qts., salt 38 lbs., potatoes 15 lbs.

On one occasion a large batch, arriving unexpectedly in cold weather and half clad, were for days without straw, the supply in the vicinity being exhausted. Besides those already sick on arrival, others soon became so. Barracks were provided as soon as possible. For a time pneumonia, variola and gangrene prevailed. It was the most fatal of our prisons.

In October, 1864, there were 9,063 prisoners, over 1,070 of whom were confined to their beds. In January, variola prevailed extensively. In March, my report gives "29.2 per cent. sick in hospital and quarters with pneumonia, variola, typhoid fever, gangrene and diarrhoea," and adds: "The condition of the patients is pitiable. Diseases nearly all of typhoid type, and much of the sickness attributable to crowd-poisoning. Clothing insufficient. Weather forbids exercise in the open air. The depressing influences incident to prison life not relieved by occupation. The Fort Fisher prisoners arrived in very cold weather, much depressed and poorly clad, many of whom were soon down with pneumonia and diarrhoea rapidly becoming typhoidal." From this time on, till June, the sickness and mortality rapidly decreased.

There were many causes for this, — less inclement weather, vastly better medical supervision under a conscientious and energetic surgeon, and, it may be added, the gradual elimination by death of the weaker and most wretched.

The inmates of the nine prisons tabulated in the "Medical History of the War," Vol. III, pp. 34-65, give an average mortality of 230.4 per thousand, in comparison with 732.6 per thousand at Andersonville, "that most fatal field of the war," as it has been so aptly called. Of the above-mentioned nine prisons Elmira was the most unhealthy, the annual mortality reaching 444 per thousand.

To the credit of our profession, South as well as North, it should be said that the medical officers at Andersonville made constant reports of the true condition of affairs there, conditions for which they do not appear to have been responsible. . . .

Occasionally our own men in hospital would charge the officers with maltreatment or cruelty, but careful investigation generally proved such charges to be unfounded, originating with some crank or bounty-jumper rebellious to discipline, who would send his garbled statement to the member from his "destrick," who, in turn, was glad enough to get rid of it by passing it over, with a strong indorsement, to the Secretary of War, and thence again indorsed to the department inspector for report.²⁰

²⁰ As a proof of the extreme readiness with which kind-hearted but injudicious civilians were constantly misled I cite an instance occurring in New Haven. When that hospital was opened, the ladies of the place were, as was everywhere the case, full of sympathy, exhibited in constant visiting and the distribution of all sorts of considerations, ready to help the poor, justly or unjustly charged. Being now a hindrance to the proper administration of the hospital, the recovery of the patients, and necessary discipline, Dr. Jewett, in self-defence, forbade admission except at stated hours, and also, that no delicacies should be distributed without approval of the ward surgeon. He was at once declared a mean-spirited master. Soon a mischievous rascal, a son of one of the ladies (or her son), who had so imposed that she had even taken him about in her own carriage, was, after repeated violations of rules, tied up by the thumbs as a punishment.

This gave the Samaritans an excellent opportunity, headed by a college professor, for a strong representation to influential friends in Washington, denouncing the surgeon's brutality. Without explanation the surgeon was not only arrested, but sent arbitrarily to Fort Columbus, pending an investigation. Finding no committee to inquire, I, as managing editor of the *New Haven Journal*, I placed one of the ward surgeons temporarily in charge, with orders to report the fact to the medical director in New York, who, by the way, made a complaint of interference with his prerogative, although he had neglected his own duty in failing to do this when the sur-

The erection of hospitals throughout the country in distant States, for the reception in each of its own wounded and sick, was a grievous mistake, the source of great abuses, involving enormous unnecessary expenditure. The cost of construction, furnishing, and transportation to and fro, were of less consequence than the fact that when once comfortably quartered near their houses great difficulty, as already said, was experienced in getting them back to duty. It became, in fact, a premium on malingerer. Their relatives, backed by the clergy and local politicians, were always at hand, and the surgeon in charge, usually a civilian of the locality whose practice now and in the future was at stake, could hardly avoid being influenced, or, should he prove firm and independent, there was always the resource of an appeal to the senator or representative. There can be no manner of doubt that an army of soldiers (in number if not in material) was thus away from the ranks, shirking duty at times of great emergency during the latter years of the war. A notable instance of this has been already mentioned, in connection with the Army of the Cumberland, after the battle of Stone River. . . .

A prevalent idea in the community at large was that whiskey was the bane of the army. Coming under my own personal observation, its immoderate use was less than in civil life. After unusual fatigue and exposure rations of spirit were distributed freely, and with benefit. As bitters (with quinine) it was, in my judgment, of inestimable service. The official reports collated in the "Medical and Surgical History of the War," Vol. III, p. 166, though not entirely unanimous, tend to confirm this belief, notwithstanding the sensational reports of chance visitors as to its demoralizing influence.

Among the officers lapses in this respect were occasionally met with, but usually in individuals who would probably have indulged still more freely in any other avocation.

In conclusion, were another great war to occur, there would of course be a corresponding expansion of the medical service. From what I have been able to see of its needs, and of which this paper gives but a meagre sketch, I am convinced that, as in the English service, the supreme authority should be an *inspector-general*, with a sufficient number of deputy inspectors, and next in rank to them, the head of the administrative bureau, either as *surgeon-general* or by any other name, so that no question of authority should intervene to minimize the value of a service which, when prosecuted with the energy and efficiency of which it is capable, can hardly be over-estimated.

Public opinion in these modern days justly demands perfection in its *ambulance corps*, meaning thereby to include all the details of military medical service. This ideal perfection can never be attained short of a corps of specially trained men such as I have spoken of in the early part of this paper. The time has passed for officers in high position to object on the score of expense or otherwise to radical changes in details of organization, which, the principle being once conceded, are all perfectly susceptible of adjustment without diminution of or interference with their authority and legitimate influence.

geon was arrested! Among other delinquencies the culprit was proved to be in the constant habit of slandering the guard, passing the night in a house of ill fame, defaming the hospital, threatening the officers, etc. To the mortification of his accusers, Dr. Jewett was promptly restored to duty.

In this country where the policy has always been (and, it is to be hoped, will long continue) the maintenance of a *skeleton* standing army only, any great conflict sprung upon us must be met by volunteers, and, of course, the appointment of its medical staff from civil life. It will hardly be contended that there is such a lack of professional ability, business aptitudes or common sense in the medical profession, outside the regular army, as to render it impracticable to find places for a fair relative proportion, in the higher grades of the service, of some of the *cranial*, as well as the tarsal, bones of the aforesaid *skeleton*.

SOME OF THE RELATIONS OF CLIMATE TO HEALTH AND DISEASE.¹

BY W. EVERETT SMITH, M.D., BOSTON,
Committee on the Distribution of Diseases.

THE COLD WEATHER (DRY AIR) THEORY OF DISEASE.

I HAVE discussed the subject of humidity thus in detail, not only because there are meteorologists who believe that *absolute* humidity has the greater influence upon health, but because upon the rejection of *relative* humidity has been reared by a diligent and conscientious observer a cold weather theory of the causation of disease²⁰ (pneumonia, bronchitis, influenza, phthisis, small-pox, scarlet fever and diphtheria), acceptable to meteorologists, but, in my opinion, fallacious.

The foundation of the whole theory rests upon the assumption, which we have proved unwarrantable, that low temperature always and necessarily means low absolute humidity. Depending upon this assumption is the further hypothesis that this low absolute humidity induces disease, not only lung, but also other diseases, by its action upon respiratory mucous membrane, because the air which is exhaled from the lungs rapidly abstracts water from the body, since it leaves the body at about the temperature of the blood, and is always "saturated" with moisture.

The best physiologists state, on the contrary, that the temperature of expired air is, as a rule, from 3° to 5° F. below the temperature of the body, and varies not only with the relative temperature of the blood and of the inspired air, but with the rate and depth of breathing.²¹ Admitting, however, that cold inspired air is expired at a warmer temperature, it does not therefore follow that it is saturated with vapor. In fact, it probably is not saturated when it leaves the body, because, although saturated in the deep-lying bronchi, it meets the lower temperature of the air the moment it strikes the buccal mucous membrane, and suffers a condensation within the mouth and throat, the vapor tension following the same law of rapid decrease as in the formation of clouds and mists in the open air. So that, although it is undoubtedly true that in a cold atmosphere the weight of vapor extracted from the respiratory mucous membrane may

¹ Read before the Massachusetts Medical Society, June 11, 1889. Concluded from page 125 of the Journal.

"The Causation of Cold Water Diseases," ibid, 1887, page 197. "The Climatic Causation of Consumption," Journal of the American Medical Association, January 1888, pages 73 and 116.

²¹ A Text Book of Physiology, M. Foster, page 265. Medical Physics, John C. Draper, 1885, page 587. The statement made by physiologists is that air is "saturated" with vapor when expired from the lungs; and such a statement is undoubtedly true.

be considerable, it by no means follows that it is so enormous in amount as has been claimed, or of disastrous results to the system.

But it is not low temperature alone which has the power of absorbing moisture from the body and respiratory organs — mark the influence upon skin, hair, nostrils, mouth, lips and throat of a high wind, causing rapid evaporation and *low relative humidity* when the temperature is high.

Indeed, to make the "dry-air" claim thoroughly consistent with itself, the argument based upon low absolute humidity should be carried one step further. Air with low absolute humidity occurs not only with low, but also with high temperatures, as is seen in Arizona, New Mexico and parts of Texas. Considering, then, for example, pneumonia, we are driven to the conclusion that it is not cold climates alone that cause the disease, but hot climates as well; and when we have reached this point we are probably nearer to the truth than are some of the cold weather theorists.

Physiological experiments upon animals have clearly shown that mere frigid temperature is not provocative of pneumonic consolidation, but that if, after an exposure to high, and then suddenly to low temperature, the animals were inoculated with the pneumococcus of Friedlander — they succumbed to the disease more readily than animals similarly inoculated without exposure to such ranges of temperature.²² The census of 1880 gives presumptive evidence that the greatest prevalence of pneumonia is in the Southern and Southwestern States; arctic voyagers do not report it to be frequent in that region, while the united testimony of clinical reports prove it to be a disease from which no climate is exempt.

Why should cold weather and low absolute humidity *per se* cause disease? Because, it is claimed, of the abstraction of the chlorides from the blood by the process of osmosis and their accumulation in the tissues. It is clear that, under such a theory, salt must be, at certain cold seasons of the year, a positive poison to the system. I confess that, unless some other factor besides dry air be given us, I can see no adequate cause, except chance, for the occurrence of any particular one of all the crop of diseases I have mentioned, some contagious and some not. So far, however, as Massachusetts at least is concerned, there are marked differences in the distribution of some of these diseases, and probably, therefore, marked differences in their causation. Our carefully kept statistics not only prove that pneumonia is less frequent and phthisis more frequent on the coast than in the interior; they also show that pneumonia does not reach its highest rate in the coldest months of winter, but in the variable months of spring.²³ Other conditions beside the inhalation of dry air, the presence of salt in the respiratory mucous membrane, and the osmosis of albuminates from the blood through these mucous membranes, are undoubtedly at work to cause such distinct diseases as phthisis and small-pox. But that salt inhaled and deposited within or upon the body is not altogether provocative of disease, is abundantly proved by the health of workmen in salt manufactories and lagoons, and their freedom from respiratory diseases as well as from rheumatism and neuralgia.

If the "dry air" theory be correct, we are indeed placed between Scylla and Charybdis. Send a con-

summative on an ocean voyage to recover health, he is exposed to greater dangers, in spite of the purer air, from phthisis, pneumonia, diphtheria or small-pox than he was at home, because he is breathing air the saline constituents of which will irritate the respiratory mucous membrane. Send him inland to recover health, where the air is cold, dry and free from salt, he is exposed to the same dangers, because of the exhalation of these same salines from the blood.

The whole confusion upon this matter lies in the assumed powers and properties of high temperature and of dry air (absolute humidity). On the one hand, the simple fact that hot air can hold more vapor than cold air, does not make it hold more at a given time and place, except under the influence of other factors. So too, although cold air is drier (absolute humidity) than hot air, we ought not to base positive arguments upon the half-truth that "cold air is always necessarily dry,"²⁴ as though there could, under no conditions except temperature, be any comparative degrees of dryness.

On the other hand, what possible inherent power, for good or for evil, can one, five or ten grains of aqueous vapor have upon us when they are considered abstractly and apart from any relation to our bodies? The very moment, however, that we begin to discuss the relations of our bodies to the air in which they live, whether its temperature be high or low or its absolute humidity high or low, at that same moment we are actually discussing the question of *relative humidity*, whether we call it by that name or not. There is no way in which we can discuss the absorption of moisture from our bodies by the air, except by a consideration of *relative humidity*. All that the "dry air" (absolute humidity) theorists have therefore done is quietly to substitute the temperature of the blood or of the body for the temperature of the air, virtually compare its vapor tension with the vapor tension of the air temperature (disregarding altogether the dew point and its vapor tension), — claim to ignore the data of *relative humidity* but calmly use its principles. If we may be allowed the unscientific phrase, they have discussed the *relative humidity* of the body, even though they are not willing to study the *relative humidity* of the air.

Since, however, the temperature of the surface of the body is modified by external atmospheric conditions, as we have seen, and the temperature of the blood similarly modified but in a different degree, it is evident that for an air temperature which is easily obtainable they have substituted body and blood temperatures that they cannot so readily obtain. If it be claimed that facts show these temperatures of the body and the blood to be fairly constant under all ordinary air temperatures and atmospheric conditions, I reply that this constancy is possible only under the play not of absolute but of *relative humidity*,²⁵ acting both directly and also through the regulatory mechanism of the nervous system, — a further proof of the value of *data of relative humidity*.

²² Henry B. Baker, M.D.: *The Causation of Cold Weather Diseases*, loc. cit., page 206.

²³ For example, with an absolute humidity of 1.676 grains of aqueous vapor the dew point will stand at 26° F. Now a dew point of 26° with an air temperature of 70° means a large evaporating power — 70% of the heat of the water will be lost before the temperature falls, — it means a much smaller evaporating power — 47% of relative humidity. The relations of our bodies to external phenomena are inherently complex; and we cannot make them simple by bare assumptions of possibilities, by speculations and inferences which are unsupported and unsupportable by facts.

Climatic Illustrations.—To what extent are our conclusions corroborated by actual climatic conditions? If, as has been claimed, cold weather be the cause not only of pneumonia, but of such dissimilar diseases as pneumonia, phthisis, measles, scarlet fever, diphtheria and small-pox, by virtue of the simple assumption that cold air is dry air (low absolute humidity), what shall we say when we find cold, dry facts to demonstrate that, although the temperature of Boston is almost identical both in curve, that is, seasonal variation, and in degree, with the temperature of Denver, the absolute humidity is far greater than that of Denver?

If the "dry-air" hypothesis be correct, Denver is more causative of pneumonia, for example, than is Boston.²² On the other hand, if it be the general similarity of the curves for absolute humidity and for temperature that determines the causation of pneumonia, then since there may be granted a superficial correspondence between these curves for Boston and for Denver, both places are equally causative of pneumonia. It is evident that both of these propositions cannot be true at the same time. If again, it be the similarity of the curves for absolute humidity and for pneumonia that determines the cause of the disease, grave doubts arise, as we have said, upon the question of facts.

To go still further, if it be low absolute humidity that is the ultimate cause of pneumonia, then Camp Thomas in Arizona and El Paso and Fort Davis in Texas, all of which have an absolute humidity nearly as low in degree and generally corresponding to that of Denver, but a much higher temperature, should be as subject to pneumonia as is Denver, while Winnemucca, Nevada, with an almost total absence of absolute humidity, but yet a high temperature, should be still more subject. Owing to other causes this may be true, but the conclusion we have drawn is both consistent and at the same time gravely inconsistent with the cold weather theory.

Again, the absolute humidity of Denver and of Mount Washington, both of them mountain elevations, shows a more marked correspondence of degree and of curve than any of our previous illustrations; but the temperature of Mount Washington is far below that of Denver. Mount Washington and Pike's Peak, however, with a nearer correspondence of temperature but a great difference in elevation and surrounding conditions (that is, local peculiarities,) have an absolute humidity very unlike. So, too, Camp Thomas, El Paso and Fort Davis have all the same approximate degree and seasonal range of temperature as Jacksonville and Norfolk, yet an absolute humidity of far less degree and range.

On the other hand, by a study of the relative humidity of these same localities we are driven to the irresistible conclusion that, apart from temperature, there are atmospheric conditions in these different places which must exert an important influence upon daily life and comfort. I cannot here go into full description of the peculiarities of each locality. It serves my present purpose of illustration to say that in every

²² That pneumonia is particularly fatal in Denver is no argument upon this point, since the fact is known to any one acquaint with the climate. The excessive altitude depresses the heart, and by its deficiency in oxygen compels a remarkable activity of lung tissue in order to oxygenate the blood thoroughly. These factors, potent to health and metabolic activity of tissue, militate positively against recovery from pneumonia with its determined pulmonary congestion and lessened quantity of aerating lung.

instance it is the data of relative humidity which serve as guide-boards to climatic characteristics essentially local—characteristics concerning which absolute humidity can tell us little or nothing. In the one case this characteristic will be the amount of sunshine, in another the amount of moisture condensed as mist, fog or actual precipitation, and in another the direction and character of the winds.²³ It is clear therefore that a low absolute does not necessarily carry with it a low relative humidity, nor does a low relative invariably mean a low absolute humidity.

Summary of Humidity.—The conclusions of this study of humidity are important. Let us assume an air temperature of 25° "saturated" with vapor, conditions easily borne by the body, to be introduced into a room through the cold air-box of a furnace. Now by heating the room to 70°, the relations of the aqueous vapor to the space it occupies have been changed; the "relative humidity of the air" will be reduced, and possibly to an unbearable degree, but the absolute humidity will remain unchanged. In other words, warming the air has changed its character, has so increased its capacity for holding vapor that it will abstract moisture from every surface with which it comes in contact.

The effects upon our systems are manifold—a parched mouth and skin, a paralyzing of the heart, a throbbing head, and a creepy, chilly sensation in the body. None of these sensations were present when the air was cold, although the absolute humidity was precisely the same; nor did absolute humidity work the change. It is clear then that in this instance it is not the low degree of absolute humidity, but the low degree of relative humidity, that may induce disease by abstracting moisture from the body.

Let us, on the other hand, assume a wet soil with its low temperature and low absolute humidity. Owing to the slight capacity of such air to hold vapor, it cannot absorb much vapor; the relative humidity is already high. The major effect of such air is to abstract heat, not moisture, from both the body and the lungs. Only when evaporation is rapid, that is, when the relative humidity is low, as on a cold, bright winter day, will cold air be markedly a drying air, unless indeed it may be said to abstract moisture by freezing it.

Barometric Data.—There is, however, another set of data that has important relations to health, but that has not yet received from physicians the attention it deserves. We have seen that whatever conditions tend to lower the capacity of the air to hold vapor, that is, to raise the relative humidity, must, in the nature of things, obstruct the orderly functions of the body. Some of these conditions are present when the barometer is falling from changes in the weather, so that bodily phenomena are somewhat the same with a low barometer as with a high relative humidity.

In addition, however, to these functional derangements, must be mentioned the influence of atmospheric pressure upon blood tension and the heart's action. When the barometer is falling, the blood pressure is lowered and the heart's action depressed. Our individual feelings are evidence of this nervous and vascular disturbance; on a first clear day following a "spell" of dull weather we are sleepy, and more easily than usual tire with moderate exercise, while on a lowering day before a storm we feel a languor and depression. To persons who are either enfeebled by pro-

²³ See Note 24.

tracted disease, suffering from shock or inflammation, or about to undergo a surgical operation, a sudden fall of barometer may bring disastrous consequences — consequences which the physician, warned by the barometer, may have averted.

Atmospheric Electricity. — Yet, after all, we are driven to the thought that neither the germ theory, nor the influence of the gross conditions of the weather that we have thus far studied, nor even the combination of these factors with inherited tendencies, occupations, modes of life, etc., offer in all respects an adequate explanation of the causation of disease. Although a high temperature and great moisture are theoretically the ideal conditions for the growth of germs, the fact remains that many of our well-marked germ diseases, both contagious and infectious, originate, or at least develop, in an atmosphere that is *cold* and either *wet*²² or relatively humid.

There is considerable probability that upon the surface of the earth, whether by the friction of revolution or of the winds, electricity is produced and stored up, the negative in the earth, the positive in the atmosphere. The air is full of this potential force,²³ and there is no phenomenon ever studied which begins to show such rapid and incessant variations. What it means, whether the force goes and what it does, are all beyond our present knowledge. Only infrequently does it become dynamic so as to manifest itself by gross outward phenomena; yet it must have a silent, ceaseless function.

This much, however, we do know. In dry air, there is very little evidence of the presence of electric force, — in fact, it is probable that if air could be made absolutely dry and kept so for any length of time, no electricity could be present in it. But in wet air and a cold temperature, conditions which we all recognize to belong to a low, wet soil, it is equally well known that the atmosphere is peculiarly full of electricity; and it is altogether probable that this surcharge is an overplus of the negative electricity of the earth rising in the air to meet somewhere its corresponding positive. My prediction is that when this intricate but fascinating subject shall be more fully studied, some connection will be established between atmospheric electricity and the phenomena of disease in, at least, cold and wet localities.

Ozone. — I omit all discussion of ozone, — that electrical form of oxygen, — because our knowledge upon the subject is so uncertain. If this gas be abundant in pure air, it would lend support to the popular opinion that it is health-giving and recuperative. But it is impossible to say whether this notion be a correct one or

²² One theory of the influence of these conditions upon at least phthisis has been offered to me in a correspondence with Professor Cleveland Abbe — that "rain and fog precipitate and wash downward germs of disease which are floating in the air; therefore the low valleys and meadows are more subject to consumption than high lands or dry interior regions." Not considering the temperature, humidity and pressure factors, but because rain and fog prevail when they vary, that the disease is developed in that locality.

²³ The amount of electricity thus stored up is enormous. At times the negative current and at times the positive current is in excess; even when neither is in excess of the other, interchange in the vast majority of cases, — on which occasions it is possible to our senses. Some of its influences upon our functions may have been noted before a thunder storm — a sense of fulness and oppression in the head, and frequently a decided nausea. Nor does the immunity in workmen in electric manufacturers and the constantly increasing use of electrical machinery when susceptible influences upon health, militate against any theory of the electrical influence of atmospheric electricity upon health; since in the former case it is the great quantity of metal in machinery and elsewhere will convey away and neutralize escaping electricity, while in the latter case it is probable that the very presence of electrical wires and points will in the same way facilitate the interchange and neutralization of atmospheric electricity overcharged.

not, since the observations that have been made have been so vitiated by the varying exposure to winds and to coal gas and sulphurous acid gas — the products of combustion — that they are without positive value. If recorded data are of any value, they tend to show that, contrary to expectation, more ozone is present in the winter than in the other seasons of the year. But I have great doubts that we know anything about the matter.

CONCLUSIONS.

(1) In tracing a connection between the weather and disease, the tendency is to go too far and ascribe to atmospheric conditions more of a causative influence than we can prove. Because a climate may expedite or inaugurate a cure is no inherent proof that a climate, even though it have the opposite atmospheric conditions, will, *per se*, cause the disease.

(2) Climate means more than the weather, and includes data concerning the contour of the land, the situation of hills and forests, and the nature and chemistry of the soil.

(3) With no reason can we measure a climate by its absolute humidity alone, or ascribe to absolute humidity the supreme control over the origin of disease. Coincidence of data does not necessarily show a causative relation.

(4) The degree of absolute humidity is more a resultant than a cause of atmospheric conditions, although it may be frequently a *mediate* cause of atmospheric changes. In no way, however, can we measure the value of absolute humidity or discuss its influence upon our bodies until we bring it into relation with something beyond itself. We are, therefore, constantly discussing *relative* humidity, — if we use the English language with its proper meaning.

(5) To assume that the weather controls health and causes disease by its influence upon the respiratory organs alone, is utterly to ignore the vascular and secretory systems of the body with their important functions. The assumption being unwarrantable, all conclusions and inferences based upon it are illusory.

(6) *Absolute* humidity, *per se*, can have no influence upon health. Its influence depends upon the temperature and accompanying atmospheric conditions. A *low absolute* humidity in *cold* air is the mediate factor in abstracting *heat*, not moisture, from our bodies. A *low absolute* humidity in *hot* air will abstract *moisture* from our bodies proportionate in amount to the degree of *relative* humidity in which our bodies live.

(7) *Relative* humidity measures the moisture-absorbing powers of the air, is an expression of our surrounding atmospheric relations, and is modified by and gives us a working notion of the direction of the winds and, at times, of the amount of sunshine. It represents conditions that are necessary to health and essentially local in their nature. It is, therefore, of great value to the physician.

(8) The best single datum to be used with the temperature is the *dew point*, since in combination with the temperature it will enable us to determine both the *absolute* and the *relative* humidity. Definitely given also the amount of sunshine or of cloud, we can form a fair idea of the hygienic value of a given locality to health.

(9) Condensed moisture has a great influence upon health. In some of its phases, it is equally as important as humidity (aqueous vapor). When in the form

of mists, exhalations and fogs it has, unfortunately, often been confounded with humidity.

10.—The chief atmospheric conditions modifying health, and therefore causing disease, are sudden and violent daily ranges in temperature, and secondarily in relative humidity.

11.—The barometer is an important but too frequently neglected instrument. A single observation of it gives us nothing that is of true value until it has been compared with preceding and succeeding inspections. The barometer should then be in a physician's office for daily use and not for mere display.

12.—We know, beyond doubt, the influence which certain low and wet localities exert upon health, but we do not understand completely the Why of this influence, so that we are not yet able to formulate with precision the general law under which our empirical observation is a particular instance.

13.—I venture the prediction that when in future years our knowledge of the electricity of the atmosphere is more completely studied we shall find in that mysterious force some solution of this problem. But I spin no gauzy theories upon the subject.

A SUCCESSFUL CASE OF GASTROTOMY FOR REMOVAL OF FOREIGN BODIES.¹

BY MAURICE H. RICHARDSON, M.D.

I WAS called to see Miss X., about thirty years of age, on Sunday, the 26th day of January, 1890. On the preceding Friday morning she had swallowed a gold pencil-case. On Saturday morning she attempted to swallow an open safety-pin of large size. This stuck in her throat, and she pushed it down with a steel crochet-needle. Soon after, she swallowed the crochet-needle and several common pins. On Sunday morning she first told of it. When I first saw her she was very comfortable. The attending physician was of the opinion that her statements were to be relied upon, and that she did actually swallow these things. I was shown a steel crochet-needle and a safety-pin, which she said were about the shape and size of the ones swallowed. She also gave a description of the gold pencil.

On physical examination nothing could be detected. There was no constitutional disturbance at this time. I advised her to be brought into the Massachusetts General Hospital, where she could be watched for a few days. On arrival at the hospital she said that she had considerable pain at times, and had had much discomfort on swallowing. There was pain on pressure in the throat and in the epigastrium. She could not localize the pain exactly, but described it as deeply seated. She was perfectly rational and composed. She was quite conscious of the gravity of the situation, and was desirous of having an operation done. From what description I could get of the articles said to have been swallowed, I thought that none of them would cause any trouble except the sharp crochet-needle. This was about five inches in length, of steel, and had a very sharp point, used in working fine thread. It did not seem to me possible for this object to pass the sharp curves in the duodenum. For this reason I was in favor of opening the stomach at once, although some twenty-four hours had elapsed since the needle had been swallowed.

¹ Read at the Meeting of the Surgical Section of the Suffolk District Medical Society, May 7, 1890.

At a consultation held on the following day, Monday, the prevailing opinion was against operative interference: first, because of doubt as to whether she had really swallowed these things; second, because there were no sufficiently urgent symptoms. The point in the discussion, at this and subsequent consultations, was as to the possibility of the straight, sharp crochet-needle passing safely through the intestine. The same evening, at the Improvement Society, after Professor Dwight's demonstration of the anatomy of the duodenum, I made several measurements with the needle, which was said to be precisely similar to the one swallowed, with reference to the possibility of its passing the curves of the duodenum. I came to the conclusion at that time that it would be very difficult, if not impossible, for this sharp instrument to get safely through this part of the intestine; and I was confirmed in my belief that the safety of the patient demanded interference.

On the following day, Tuesday, the temperature rose to 103° at night, and there was considerable discomfort and pain. I therefore decided to explore the abdomen on the following day.

Wednesday, January 29th, I opened the abdominal cavity in the median line, between the ensiform cartilage and the umbilicus, by an incision four inches in length. There was a thick layer of fat at this point, which made the exposure of the stomach quite difficult. The pyloric end of the stomach was seized, and drawn out of the abdominal wound. I felt at once the sharp point of some foreign body, which I supposed to be the needle. On getting it well between my fingers, I found that it was the open safety-pin sticking into and through the posterior walls of the stomach, just above the pylorus. This I removed through a longitudinal opening, half an inch in length, in the anterior wall of the stomach, two inches from the pylorus. I then explored the stomach itself with various instruments, to feel, if possible, any other foreign bodies. Nothing could be felt in this manner or by digital examination. I next explored, as carefully as possible, the duodenum and the intestines as far down as the ileo-cecal valve. Nothing abnormal whatever could be felt. Thinking the needle must be in the duodenum, I made another careful examination of that region and satisfied myself that nothing was there, although from the subsequent history of the case I am convinced that I was mistaken. Previous to the digital exploration of the stomach and intestines I made a temporary suture of the opening through which the safety-pin had been extracted. At the close of the exploration this was in such good shape and held so well that I left it. The patient recovered well from the ether and from the operation. Nothing had been taken by the mouth for twelve hours preceding the operation, and nothing escaped from the stomach while the pin was being removed. Great care had been exercised in the preparation of the patient and in the sterilization of the hands of the surgeon and assistant.

The temperature on the day of admission, in the evening, was 100°; on the following night, 102 1-2°; on Tuesday, 103°; on the night of the operation, 102°; and on the following day, 101°; whence it went quickly to a normal line.

On the 4th of February she passed the pencil. It was of gold, with rounded ends, and about a quarter of an inch in diameter. There was nothing about it

which would in any way hinder its passage through the entire alimentary canal. On the 14th of February she passed one of the common pins.

The patient rapidly recovered her strength after the operation, and was soon able to take abundant food by the mouth. The stitches were removed at the end of the seventh day.

On the 7th of February, nine days after the operation, the temperature began to go up, and a slightly fetid discharge was noticed from the dressing. On exploring the wound, at least a pint and a half of foul pus, with distinctly fecal odor, was evacuated from the depths of the wound. Exploration with the probe showed that the abscess was a localized peritonitis, and that the pus had become infected in some way from the alimentary canal. I came to the conclusion that the needle had perforated some part of the intestine high up, probably the lower part of the curve of the duodenum. I have seen no reason as yet to change this opinion. I fully expected to find the needle in the abscess cavity, but although I explored very thoroughly, nothing could be felt suggestive of a foreign body. By careful irrigation the abscess rapidly closed, and on the 10th of March the wound was entirely healed. During this time she had no unpleasant sensations whatever, except a feeling of discomfort about the epigastrium, which she called dyspepsia. Since leaving the hospital she has been in the best of health and spirits.

The most interesting point in connection with this case is, whether it is possible for a steel needle, five inches in length, with a sharp point and a hook on one end, to pass through the duodenum. I think it doubtful whether it would go through the rest of the intestine, even, and that it is almost impossible for such a thing to get as far as the jejunum. I was able by manipulations to pass through the duodenum of a cadaver a director of about this length, but the point of an ordinary director is much less sharp than the point of this needle.

There is so little danger in opening the stomach that I should not hesitate to resort to this procedure in all cases where there is any question as to the possibility of the foreign body getting safely through. The experiments of Senn, and very numerous clinical cases, have shown us that substances of most remarkable shape and size may successfully pass through the intestines; so that one would hesitate before saying that an object could not pass through which had successfully entered the stomach. For the purpose of removing the open safety-pin, which apparently had caused all the trouble there was in the stomach, and the pencil and the common pins, I should not have thought for a moment of performing this operation. I did, however, think the presence of the sharp crochet-needle a great menace to the patient's life, and in a similar case, where it was certain that the patient had swallowed an object five inches in length, sharp on one end, I should not hesitate immediately to perform gastrotomy, which is one of the safest of abdominal operations.

— Dr. William Lomax, an aged and wealthy physician of Marion, Ill., has given his entire estate, supposed to amount to \$100,000, to the Medical College of Indiana. The college has been reorganized to meet the views of Dr. Lomax, and is chargeable with a small annuity during the life of the doctor and his wife.

EXCISION OF THE KNEE FOR ANGULAR ANCHYLOYSIS: REPORT OF FOUR CASES.

BY ROBERT W. LOVETT, M.D.

ANGULAR ankylosis of the knee-joint, from whatever cause it arises, is a particularly disabling and distressing deformity. Especially is this the case in women, with whom walking without crutches is rendered impossible, for the reason that when one leg is so much shorter than the other, on account of the bend at the knee, the skirts would drag on the ground every time that the short leg was stepped upon, to an extent that would make progress impossible. With men the deformity is unsightly and the occasion of much discomfort, but it is not the positively disabling affection that it is in women.

Operations for the relief of the condition are so simple, and so satisfactory in their results, that the subject seems to merit more consideration than it ordinarily receives.

The following cases are of interest chiefly as a group, because they represent the same deformity due to three widely-differing causes, and because the affection was so severe that each of the patients was crippled by it, and gladly consented to any operation which promised relief.

In each of the cases excision was done, with the removal of a wedge of bone from the affected knee, so that the limb could be straightened. Two other operations are recommended by modern surgical writers, for the relief of this condition, *bisection forcée* and osteotomy of the femur.

In all of these cases an attempt was made, under ether, to straighten the limb by manual or instrumental means before resorting to a cutting operation, but no justifiable amount of force produced any effect. Had the ankylosis been of more recent date, this method might have proved useful, but during the operation the ankylosis was seen to be bony in all but the last case.

The operation of osteotomy above the condyles of the femur, with subsequent transverse fracture of the bone, has been recommended by some French and German writers;¹ but it has obvious objections in cases of angular ankylosis at the knee, unless the deformity is very slight, because when the leg is straightened, the lower fragment of the femur, below the fracture, is carried forward, and forms an unsightly bony prominence on the front of the leg, which is very marked in cases of severe deformity.

Proceeding without further comment to the cases in question, they were as follows:

CASE I. Mary R., age sixteen. Angular ankylosis of the knee, due to infantile paralysis.

The girl suffered from an attack of infantile paralysis in early childhood, which attacked the entire right leg; and the resulting disability was so great that, for a time, the limb was useless, and ankylosis of the knee in a flexed position resulted in the course of time. When seen, she was unable to bear any weight on the limb, on account of the flexion of the knee, which was bent about sixty degrees. There was a certain amount of knock-knee present, due to the overgrowth of the internal condyle of the femur. Motion at the knee was absent; and the whole limb was wasted, blue and cold, and the patient unable to walk without crutches.

¹ Revue d'Orthopédie, March, 1890.

November 6, 1888. The patient was etherized, and a formal excision was done, removing a wedge of bone of such a shape that the knee could be extended, and the knock-knee corrected as well. The bones were nailed together, and an antiseptic dressing applied, which was incased in plaster-of-Paris.

November 12th. The limb was dressed, on account of extensive staining of the outside dressing.

December 8th. The nails were removed, and the wound was found to be healed by first intention. Union was perfect.

September 12, 1889. The patient had a straight leg, with firm union.

At the present time she can walk without a crutch, and has a perfectly useful stiff leg, which is much more serviceable to her than any apparatus could have been.

CASE II. Innis T., age eighteen. Ankylosis, due to tumor albus.

White swelling of the knee occurred at the age of four. Abscesses formed and discharged; but she was treated for four years, and at the end of that time, it is reported that the leg was straight. Flexion, however, came on in the intervening years; and in March, 1889, the knee was flexed to forty-five degrees, and was fixed in that position by an ankylosis apparently bony. There was slight subluxation of the tibia. The disease was apparently quiescent; but the leg was almost useless for walking, and the patient was obliged to use two crutches.

March 27, 1889. The patient was etherized, and a wedge of bone was excised from the knee, which enabled the leg to be straightened. The two bony surfaces were nailed together by ordinary French box-nails, and the wound sewed up. A permanent dressing was applied, and the leg incased in plaster-of-Paris.

The wound was not dressed until April 15th, when it was found in excellent condition, and the nails were removed. A plaster bandage was kept on for two months more, and the convalescence was uneventful.

The leg is now straight and useful, with a shortening of two to three inches, due in part to the early retarded growth of the leg, and in part to the removal of the bony substance.

CASE III. Lizzie C., age seventeen. Ankylosis, due to rheumatic synovitis.

In 1887 the patient had a severe attack of rheumatism in the knee following exposure to cold. She was in bed six months with this, and at the end of that time had a stiff knee, which was fixed at a right angle. Pain and all symptoms had disappeared, but the limb was useless, and walking was only possible by the aid of crutches. There was no subluxation of the tibia, but the knee was perfectly stiff and motion was impossible.

March 27, 1890. The patient was etherized and an attempt made to extend the knee by force, but it was impossible to do so, and a wedge of bone was excised from the knee and the leg brought into position and held by nails, as in the preceding case. A permanent dressing was applied and incased in a plaster shell, and the limb was undisturbed until April 15th, when union was found to have taken place.

May 4th. The nails were removed, and the convalescence was steady and uninterrupted.

The result was very satisfactory, and a stiff, useful leg resulted, perfectly straight, with but little short-

ening. As early as June the patient was able to bear some weight on the leg.

CASE IV. Lilian H., age seventeen. Ankylosis, due to tumor albus.

At two years of age the patient had tumor albus of the right knee which became particularly troublesome at about the age of eight, when abscesses formed and plaster bandages were applied. But treatment was not carried out faithfully, and the knee flexed to a right angle and became fixed there, and was of no use in walking.

The examination showed the knee flexed to a right angle and allowing about ten degrees of motion, when it was stopped by a bony click in flexion and extension. Subluxation of the tibia was very marked, and measurement showed about five inches shortening in the limb.

April 16th. The patient was etherized, and after an ineffectual attempt at straightening the limb by the use of Dr. Bradford's lever a formal excision was done and a wedge of bone removed. The bones were not nailed nor wired together, and the usual dressing was applied.

April 30th. The incision was healed by first intention, and the convalescence has been steady and satisfactory. At the present writing the limb is still in plaster, but weight can be borne on it in walking, and it promises to be a useful leg, with surprisingly little more shortening than it showed in the flexed position, now measuring only a little over five inches shortening.

The operation in each case was done by the semilunar incision, and except in Case IV the patella was left undisturbed. In that case it was removed, as it was much increased in size.

The technique of the operation was perfectly simple, and was done without the Esmarch bandage in every case, because in that way the amount of after-bleeding is much diminished. When the bandage is used after its removal the paralyzed capillary vessels pour out blood and serum for hours, often at once staining through the outer layers of the dressing and necessitating redressing, while in operating without the bandage and tourniquet the bleeding has proved very slight, and only a few small vessels have been tied.

After the dissection of the flap a wedge of bone was removed with the saw and the bony surfaces brought in contact. If the limb was not then in a straight line another slice of bone was removed to bring the bony surface into the proper plane.

Nailing the bones together was, perhaps, as satisfactory a means of fixation as any, but it was far from secure, and was attended by much bother in extracting the nails when the skin had healed over them, as it did in these cases. It has apparently answered just as well to let the bones lie in contact without any nailing or wiring, as the dressing is to be left undisturbed for some weeks if possible.

A bone drain was used in each case, which was absorbed readily, leaving temporarily, however, a slight sinus behind it which was of no account. All the cases were free from septic symptoms and pain, and were but little affected by the length of the operation.

— San Francisco is to have a new quarantine station, for which Congress has appropriated \$125,000.

FOOD, DRUGS AND THEIR ADULTERATIONS.

BY R. F. DAVENPORT, M.D.

ANALYSIS OF TINNED MEATS.¹

DR. WARDEN and the other chemists of the laboratory of the chemical examiners' department, at Calcutta, have recently reported the results of their examinations of seven brands of canned meats. Compared with König's analyses of fresh meat, it appears that, while the moisture in the canned meat is in most cases less, the fat is usually more than is present in fresh meat. The albuminoids also are higher in the canned meats than in the fresh; but on making a comparison when both are freed from moisture and fat, the following differences appear:

Mean of all tinned beef	87.062
" " " mutton	87.187
" " fresh cow and ox beef	93.936
" " " mutton	93.812
" " tinned meat samples	87.124
" " fresh "	93.874

The canned samples are distinctly lower in albuminoids than the fresh meats, and taking that as representing their nutritive value, are of so much less worth. These results, then, generally confirm those of previous analyses, indicating the lower nutritive value of tinned as compared with fresh meat.

COMMERCIAL PEPTONES.²

They are generally prepared by the action of pepsin and hydrochloric acid upon meat, and vary greatly in their composition. Some are a light yellow amorphous powder, such as Witte's and Grüber's, and consist almost entirely of peptic albumoses, with but a small portion of true peptone. Some preparations appear as a thick, moist, yellowish-brown mass, with no trace of true peptone, such as Kemmerich's and Koch's. Others, fluid as a syrup contain only a small proportion of peptone, yet have an aroma of cocked meat, and are rich in stimulating extractives.

The recent results obtained by Dr. S. Martin confirm the former observations of Professor Kühne that most of the protein substances in commercial peptones consist, not of true peptone, as physiological chemists now understand that term, but of its immediate precursor in peptonic digestion in the stomach, which they term albumoses. It may be that the administration of artificial food in the form of albumoses has the advantage of still leaving to the stomach the slight labor of completing their conversion into peptones. Yet this would not be true unless peptone is the form in which proteinoids are absorbed.

The heterogeneous form in which proteinoids are usually presented to the stomach for conversion into albumoses and peptones are the coagulated myosin of meats, the casein of milk, the partially coagulated gluten of bread, and the large glass of vegetable albumoses which differ from animal varieties in that they probably have to undergo some change before assimilation. It has generally been accepted that peptone, the end product of gastric digestion, is the particular form in which protein food is assimilated, but it is not now considered as proven, from the fact that the substances used in the former feeding experiments are now known not to have been peptones as now understood, but rather albumoses.

¹ Chemical News, June, 1890, pp. 291, 303.² British Medical Journal, December 7, 1889, p. 126.

Considering now for convenience that the term peptone shall include the soluble products of gastric digestion, both albumoses and true peptone, then Brücke stands alone in denying that proteinoids are absorbed as peptones. The experiments of Plosz and Maly seem to indicate that such peptone has the same nutritive value with dogs as the ordinary proteinoids of their food at least for short periods. It does not, however, hold so true for prolonged feeding, for Voit found that rats fed upon peptones, fat and carbohydrates succumbed at the end of seven months. His results, however, may admit of several explanations. Kühne found that in gastric digestion two kinds of peptones were formed. One of them with pancreatic juice would not, and the other would split up into leucine and tyrosin, products so far as at present known of no nutritive value. During natural digestion there is at no time any considerable quantity of peptone present in the stomach. It is absorbed or passed in solution through the pylorus as fast as formed. If, therefore, a larger quantity of peptone were given at once than could readily be absorbed, and thus a considerable portion of it passed the pylorus, and were acted upon by the pancreatic juice being thus changed into leucine and tyrosin, its nutritive value would then be largely reduced. It may well be that thus much of the peptones given during prolonged experiments have in this manner been wasted. This possibility is well worth considering in feeding patients with peptones. The effect, however, of pancreatic admixture is probably avoided in rectal administration. The partially peptonized foods also avoid the loss incident to the presence of overmuch peptone.

Kühne finds the peptones formed by pancreatic digestion differ in some respects from those formed by the gastric, and he therefore calls them tryptones. These differences seem to be more nutritive than chemical. Peptone, although present in stomach and intestines, are not to be found within the tissues themselves, nor in the lymph and venous blood, and it is doubtful if in traces in the arterial as has been claimed. They must, therefore, have been changed at least in the act of absorption. Hofmeister has shown that it happens within the mucous membranes, and Ott that it changes into serum albumin. Frailein, Popoff and Brücke have recently shown that peptones may be changed by the action of mucous membranes into a nutritive fluid for sustaining the continued action of a frog's heart, while pancreatic tryptone, neither before or after such action, would serve this purpose.

PROXIMATE ANALYSIS OF COMMERCIAL PEPTONES.³

M. Denayer proposed the following scheme of separation for the important albuminoiodides of these preparations, especially the gelatine-chondrin, as he calls one of them. They are all so closely allied that but few reagents will serve to cause a separation with comparative ease and rapidity. His plan is to first add to the solution of the peptone some double iodide of mercury and potassium, which he claims will precipitate only the albumose. The filtrate, after concentration, is treated with an excess of a saturated solution of ammonium sulphate, and then gradually brought to a boil. The gelatine is thus coagulated upon the walls of the containing vessel. Rapid washing with cold water will remove the small quantity of entangled iodide, but still leaves a little sulphate. The precipi-

³ Revue Internationale des Falsifications, Pt. x, p. 165.

tate is then dried, weighed, and then dissolved in hot water, and the ammonium sulphate present determined by means of a normal standard solution of barium chloride, and deducted from the first weight. This is apparently the novel feature of his scheme. He secondly precipitates the albumoses and gelatine by saturating some of the solution with ammonium sulphate. Washes them upon a tared filter with some more of the ammonium sulphate solution, dries and weighs the precipitate, and then determines and deducts the adhering sulphate as before. He, thirdly, having exhausted a portion of the peptone with 95 per cent. alcohol of all of its kreatin and other extractive bases, which he determines in the evaporated residue of the alcoholic solution, dissolves the peptone in water, and then precipitates the albumoses, gelatine and peptone with phospho-tungstic acid. This is dried, weighed, ignited, and the ash deducted from its first weight. From the three results obtained by these three precipitations, the percentages of albumose, gelatine and peptone are readily deduced. The author's results agreeing closely with those obtained by the estimation of the nitrogen. The following results thus obtained show the relative composition of some preparations:

	Peptone of purified meat albumen.	Peptone of egg albumin. ^a	Peptone direct from meat.
Peptone	37.675	34.700	25.857
Albumose	31.300	53.200	15.964
Gelatine	none	none	9.826
Definite comp.	5.525	5.930	29.972
Mineral salts	8.285	1.625	18.386
Water	10.330	4.625	none
Insoluble matter	9.965	3.980	none

SHOULD BEER BE DRUNK OUT OF GLASS?

A spirited contest has for some while been waged in Germany between the beer-glass and the stone-mug factions. Dr. Schultz claims to have established, by a very extended series of experiments, that beer, by as little as five minutes, standing in any glass, even when cold and in the dark, will be materially affected both in taste and odor. He sustains his claims by trial tests confirmed by some one hundred persons. The change, he thinks, is due to the slight solubility of the glass substance in the beer. This is of further importance from the fact that the glass most generally used contains lead, which has been added for its better and more easy manipulation in manufacture. From a series of experiments made upon glasses obtained from the leading sources of supply, he determined that one cubic centimetre of beer, by five minutes standing in glass, dissolved 6 to 26 ten-millionths of a milligramme of the glass substance containing 0 to 48 thousand millionths of a milligramme of lead oxide. This small quantity of glass substance he claims affects the taste of the beer, and if it also contains this lead, renders it objectionable from sanitary reasons. He recommends for use as a normal test a drinking vessel, whereby one can surely and easily determine the fitness or unfitness of any other vessel, a silver mug gilded upon its inner surface. The beer to be first tasted out of the silver mug, and then out of the other vessel. He gives the following comparative scale of fitness for beer vessels as made out of different material: All lead-glazed mugs are to be wholly excluded. Covered salt-glazed stone mugs he ranks as good, but tin ones as better, and gold-lined silver mugs as the best.

^a Mittheil. d. Versuchstation f. Brauerei u. Malzerei in Wien.

Hard lead-free glass he ranks as poor, but soft-pressed glass as still poorer, and poorest of all lead glass, either pressed or blown. Porcelain, even that made at Meissen, he thinks not serviceable. Wood mugs are doubtful on account of the pitch varnish, which, even if it should not flavor the beer, yet is liable to induce loss of sleep and headache.

Dr. Schultz's conclusions have been discussed and disputed by Prof. Dr. F. Linke.^b He claiming that, according to Schultz's own showing, 20,800 litres of beer out of the very worse kind of lead beer-glass must be drunk within fifty-seven years, in order to take in even one milligramme of lead oxide into the body of one drinking a litre of beer a day. From an average quality of lead glass, it would take 74,000 litres and two hundred and three years to accomplish the same. Moreover, he claims that Schultz's lead quantities are seventy-six times too great, and that, therefore, it would require that much longer time to imbibe that small amount of lead.

A NEW BUTTER SUBSTITUTE, FAT FROM AFRICA.^c

M. Heckel and Schlagdenhauffer have discovered and reported upon a certain Spanish broom-like bush, native of the west coast of Africa, which belongs to the Polygalaceae family, and to which they have given the specific name of butyracetum. The native name of the bush is Malonkang or Ankakuki. Its seeds yield 17.5 per cent. of a yellowish butter-like fat of a very agreeable nutty flavor, and which could well serve as a substitute for butter. The fat softens between 28 and 30° C., beginning to melt at 35°, but does not become fluid below 52°. Upon cooling it remains fluid for a long time, only beginning to solidify at 33°, when it regains its original consistency. Its density at between 35 and 38° C. is 0.904. It saponifies very easily with alkalies, and contains 31.5 per cent. olein, 4.8 per cent. free palmitic acid, 57.54 per cent. palmitin and 6.16 per cent. myristin. It contains small quantities of formic and acetic acids, but no butyric or valeric acid, and therefore it does not easily become rancid.

CONGO COFFEE.^d

L. Reuter reports that Congo coffee contains no caffeine, and that its coloring substance is also different from the ordinary coffee. He does not, however, say whether he found it to contain any other alkaloid.

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

GEORGE H. MONKS, M.D., SECRETARY.

REGULAR Meeting, Wednesday evening, May 2d, DR. E. H. BRADFORD in the chair.

DR. C. B. PORTER showed a patient upon whom had been performed

AMPUTATION AT THE SHOULDER-JOINT FOR SARCOMA.

The result was a very satisfactory one, and the wound was practically healed. The history of the case is as follows:

^a In Sprechsaal, Organ der Porcellan, Glas. u. Thouwaaren Industrie, 1890, No. 17.

^b Jour. Pharm. et Chém., 1890, 148.

^c Pharm. Ztg., 1890, xxiv, 473.

The patient, a man of twenty-five, during November, noticed in his forearm for the first time a bunch about three inches above the lower end of the ulna. He had sprained his wrist some time before. The swelling increased rapidly in size, and the patient went to the Out-patient Department of the Massachusetts General Hospital for advice. At that time there was a general enlargement of the lower end of the forearm, which seemed to include both radius and ulna. The swelling was the size of a hen's egg. There were no enlarged glands. There was some pain in the arm and stiffness of the fingers. Amputation was advised, but the patient would not consent to it. He left the hospital, and on the next day allowed his family physician to enucleate the tumor. Some days later the patient appeared at the hospital, the wound from the operation being in a highly inflamed state. As soon as the acuteness of the inflammation had subsided under appropriate treatment, the patient agreed to an amputation, and Dr. Porter took off the limb just above the condyles of the humerus. Before the operation wound had entirely healed, there was a recurrence of the disease in the stump. In the mean time the patient had left the hospital. He returned on April 22d, requesting an operation, and stating that he preferred to die in that way than by the terrible pain with which he was tortured. Besides the nodules at the end of the stump, there was a large mass of disease in the axilla and a fulness in the supra-clavicular space. There was a general tenderness about the shoulder, stump and axilla. After consultation with Drs. Warren, Beach and Richardson, Dr. Porter decided to amputate at the shoulder-joint. On April 23d, therefore, ether was given to the patient; and, as a preliminary step, the subclavian was tied in its third part on the subclavian triangle. Amputation at the shoulder was then done by the "deltoid flap" method. This flap was formed by transfixion, after which the head of the bone was disarticulated, and a short axillary flap was made. The incision was prolonged along the lower edge of the clavicle and the pectoral muscles turned downwards and inwards. From beneath them a large mass, including glands and fat, was dissected out. The bleeding gave no great trouble. The flaps were united with silk sutures and bone drains were inserted. The operation lasted one hour and a half. A dry dressing, with compression. Six days later the dressings were removed for the first time, and the wound had practically united by first intention, the drainage-tubes having been absorbed. The stitches were taken out, and a light, dry dressing was applied. Two or three days later the patient was up and about the ward. A microscopic examination (by Dr. W. F. Whitney) of the affected parts of the stump and glands removed showed them to be made up principally of masses of large round cells, with a little intercellular substance. A slightly lobulated character was given them by fine bands of connective tissue. The diagnosis was "large round-celled sarcoma."

DR. J. W. ELLIOT said: I happened to see this patient in the Out-Patient Department four weeks after the injury to his wrist, and there was a swelling there which in appearance resembled a swollen Colles's fracture, and yet the bone itself was so thickened and so widened that we all believed that it was a case of sarcoma of the wrist. By a very strange coincidence, while in charge of Dr. Porter's ward this winter, I

had a case almost exactly the same as this. I happened to have seen the patient at my office October 26th, and he had a small epithelioma on the outside of the arm. This epithelial growth was removed from the arm in November, by Dr. Cabot, at the hospital. Later, the patient came to my office again, and there was then a large mass of glands in the axilla. He was admitted to Dr. Porter's ward in the hospital when I was in charge temporarily. I did almost the same operation as Dr. Porter did in his case. Instead of ligaturing the subclavian, however, I opened the axilla, cut away the pectoralis major and minor, and tied the axillary artery in its very upper portion; then I dissected out the mass of glands in the same manner as Dr. Porter did, and amputated the arm at the shoulder. This patient recovered, and is still without return, I believe.

When the question of amputation at the shoulder-joint came up, there were various opinions as to whether it would pay to amputate for such disease; and, of course, the serious nature of the operation and probability of return were brought up against it; but one argument, which Dr. Porter brought forward, seemed to me to be a good one, and that is, that if you leave the arm on (it was suggested by one of the surgeons to take out the axillary glands, and leave the arm so that the patient might use it as long as possible), it would very shortly begin to swell, and be not only a useless member but a very cumbersome one; and, as the other arguments seemed to me very evenly balanced, this had great weight in making up my mind to operate as I did; and as three months have elapsed and the disease has not returned, I am very glad the operation was done.

DR. PORTER: One word explanatory of why I tied the subclavian before the operation. It was for the sake of saving blood. It seemed to me that it was not a difficult operation to do, that it would control the hemorrhage, and that if, on the other hand, we tied the brachial at the point where it would be divided in the ordinary amputation at the shoulder-joint it would delay the operation, and also necessitate considerable loss of blood. The operation was completed in seven minutes, and the bleeding was very slight.

I think what Dr. Elliot spoke of as one of the principal arguments for the removal of an offending member like this is an important consideration; for where the axilla has once become invaded by glands, the pressure upon the circulation and nerves produces so much swelling and pain that the limb is a constant source of trouble to the patient. This patient had been using large quantities of morphine and of stimulants to overcome the pain. The morphia was discontinued after the first day following the operation, and the patient now states that he has no pain.

DR. O. K. NEWELL: In connection with Dr. Elliot's operation, I think there is one advantage in tying the axillary high in this operation and that is, that you avoid the risk of wounding the thoracic duct when the operation is on the left side. That is one of Billroth's precautions.

DR. M. H. RICHARDSON: I have made a great many dissections of the duct with reference to the special danger of cutting it in operating. I saw the duct cut once by one of the students in Dr. Porter's operative course. I think it goes much higher than the body of the sixth cervical vertebra sometimes, and is well protected by the oesophagus, and then takes a

turn to the left. I never saw a case in which the thoracic duct came near the third part of the artery.

DR. NEWELL: That is a point always taken in operative courses in Europe. The thoracic duct empties at the junction of the internal jugular and subclavian veins. In the living subject it may have a very tortuous course, and wind around in that space, so that it is always to be seen in the subclavian triangle. A simple and safer procedure is to ligate the axillary high up.

DR. PORTER: From a surgical standpoint, ligation of the axillary high is a much more difficult operation than is ligation of the subclavian in the third part, with the thoracic duct practically separated from the artery by the thickness of the scalenus anticus. It seems to me if the anatomy of the part is followed correctly, there is no danger of injuring the thoracic duct in the ligation of the subclavian in its third part.

DR. BRADFORD: Were there any enlarged glands above the clavicle in this case?

DR. PORTER: One gland was found, and examination proved that it was infiltrated with sarcoma cells in the same way as the glands in the axilla.

DR. ELLIOT: As I watched Dr. Porter's operation, it seemed to me it was a very even question as to whether it was better to tie the subclavian first or not. In my operation I simply opened the axilla, took off the pectoralis major and minor, and, before I had dissected away the glands at all, I saw the artery high above the glands under the clavicle and tied it very easily. Certainly there was no trouble about hemorrhage, and I could have tied it higher, if necessary, in the same wound.

DR. G. H. MONKS demonstrated

A NEW METHOD FOR THE TREATMENT OF INJURIES TO THE SHOULDER,

and showed several patients in whose cases he had, with the co-operation of Dr. A. K. Stone, successfully employed it. About twenty-five cases were reported, including some in which rheumatism undoubtedly played a prominent part. In most of the cases the ordinary methods of treatment had been tried in vain. The result was a more or less perfect cure in about two-thirds of all cases tried in a period of time varying from a few days to a few weeks. The most hopeful cases were those which were purely traumatic. The principle involved in the treatment was that the shoulder is more perfectly in a condition of actual rest when the arm is supported at right angles to the trunk, than when the elbow is kept at the side, because (1) the weight of the upper extremity is thus entirely taken off the shoulder, (2) the deltoid and other structures covering the joints are relaxed, and (3) the circumflex nerve and other deeply seated structures are relieved from pressure. In applying this method of treatment, the whole weight of the upper extremity is taken upon a platform-shaped splint, which is supported by a firm band of webbing passing over the other shoulder. The cases for which this form of treatment is especially adapted are those where the prominent symptoms are persistent pain and tenderness in the shoulder, or inability to raise the elbow from the side.

DR. RICHARDSON said: It seems to me that any apparatus or method of treatment, which offers any benefit in these obstinate cases of pain in the shoulder, will be very welcome indeed to the profession. I

would like to ask as to the effect of this in that condition of the shoulder described by Dr. T. B. Curtis as "periarthritis." I do not refer to rheumatic cases, but to cases in which, on lifting the arm, the shoulder goes with it.

DR. MONKS: Unfortunately I have not thus far had a case of that kind.

DR. RICHARDSON: That class has been most obstinate in my experience. I do not remember any good results by breaking up adhesions, or by any operative procedure. I have seen stiff shoulders result, and in one case, caries of the joint. In many of these cases, it seems to me from my observations, that the pain is due to inflammation of a large bursa under the deltoid near the head of the humerus, which is probably, like many other deeply seated bursa, frequently inflamed. It seems to me that Dr. Monks's apparatus would relax the pressure on the bursa better than anything else.

DR. BRADFORD: I think we can hardly recognize of how much value this may be. The mechanical appliances that have been used for these cases of painful shoulder have been very few. Dr. Marsden, of Roxbury, devised a somewhat similar splint for cases of fracture. The splint was to exert traction much on the same principle as in Buck's extension for fractures of the femur. It was used at the time of the war to a limited extent, and is figured in the surgical records of the War of the Rebellion. Dr. Thomas, of Liverpool, has a splint which he has used, I don't know with how much success. Then, of course, there is the cushion devised by Strohmeyer. The nearest approach to the splint of Dr. Monks is the appliance of Dr. Taylor, of New York, for cases of paralysis of the deltoid in children. I remember seeing a patient for whom he made a very pretty appliance which was worn by the child about six months. It was used for infantile paralysis of the deltoid, but I think without any benefit. It was not worn at night. Supposing the cases reported to be sprains of the shoulder-joint, slight synovitis, the method seems to be very rational, so rational that it is strange it has never been done before. It relaxes the muscle, and it is spasm of the muscle which causes pain in the earlier stages. I should think it might be used in some of the more chronic cases.

DR. MONKS: The special kind of splint which has been used in most of the cases reported is one which was designed, at my request, by Dr. Stone.

DR. ELLIOT showed

A PIECE OF INTESTINE FOUR AND A HALF INCHES LONG WITH SIX GUN-SHOT HOLES, and said: The bullet went in and out three times. The specimen is from a case of gun-shot wound in a gentleman who was shot at short distance with a revolver. I do not remember the calibre, but the wound in the abdomen was so large that in the exploration to determine if it was a penetrating wound, my finger went directly into the abdominal cavity, and with the scissors I did a laparotomy at once.

DR. M. H. RICHARDSON reported

A CASE OF GASTROTOMY FOR THE REMOVAL OF FOREIGN BODIES.¹

DR. BRADFORD: I wish to mention a case which was related to me by a physician from one of the neighboring towns: A child was brought to him who

¹ See page 177 of the Journal.

had swallowed an ordinary shawl-pin with a large beaded head. The patient was brought with the point of the pin protruding through the abdomen. The mother wanted the doctor to take out the pin. He was rather puzzled what to do, but finally he pulled the pin out firmly, and then with a pair of bone-pliers he cut it off. A couple of days later the head was passed by rectum. The case is interesting simply as showing what ingenuity may do to help one out.

Dr. RICHARDSON: I have collected all the cases ever published of foreign bodies. In a great many the sharp instrument worked out. It ought to be said that while a certain number of these do work out safely, a large number are fatal either from peritonitis or perforation of a large blood vessel.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED Meeting, May 19, 1890. The President, **GEORGE T. HARRISON, M.D.**, in the chair.

Dr. PAUL GIBIER, Director of the New York Pasteur Institute, read a paper on

BESTACTIONS PRODUCED BY THE ANTI-HYDROPHOBIC PASTEUR INOCULATIONS, AS DESCRIBED BY INOCULATED SUBJECTS.

He said that following in the steps of those connected with other anti-rabic institutions, in order to ward against a possible accidental inoculation during these daily manipulations of virulent matter, he had inoculated himself and two of his assistants. A lad attached to the laboratory was also inoculated; but while the latter complained only of a local sensibility, of fatigue, and of a little nocturnal disturbance, the physician, being more accustomed to observation, noted several other points about the effects of the inoculations which seemed worthy of record.

The series of inoculations began March 27, 1890, with marrow of the fourteenth day, and ended April 10th, with the matter of the second day. The subcutaneous injections of the first four days were followed by a slight irritation which, in one of the subjects, extended as far as local redness of the integument, but without induration. During the night sleep was somewhat disturbed by the sensitiveness of the seat of inoculation in the lumbar region; and for the first ten days the symptoms were about the same. The body temperature rose slightly; but whether this mild febrile reaction was due to the irritation of the injected matter or was the result of the slight inflammation caused by the injection itself, it was impossible to say. These symptoms were considerably modified by hot baths of long duration. Towards the tenth day the tissues seemed to have accustomed themselves to the injected liquid, the reaction was less acute, the pain decreased; and three days after the last injection there remained scarcely any local trace of the fifteen injections made on each side.

At this point Dr. Gibier took up the question of the manner in which immunity is obtained, and stated that in a book of his published last year in Paris he had offered the explanation that it was probably the result of a sort of automatic memory on the part of the living cells of the body. Each time these cells were attacked by a malady, he said, they recalled how they had gotten rid of the intruding microbe which attacked them, and when next assailed they knew immediately

what measures were necessary to prevent the enemy from obtaining a foothold. In this connection he remarked that the recent work by Metchnikoff on the part played by the white corpuscles in the case of inflammation produced by bacteria certainly seemed to afford strong evidence of the correctness of this hypothesis.

In order that the nervous centres should be protected against a mortal attack of rabies it was necessary (for the purpose of forestalling the progress of the microbe) that other microbes of the same species, but attenuated, should be placed in contact with the cells of the spinal cord and brain. The first subcutaneous injections were made with the matter the prolonged desiccation of which had caused its virulence to disappear; but it was not unreasonable to admit that the nerve cells must be influenced in a measure by the ptomaines secreted by the hydrophobic microbe, and that this is likely to give it a certain amount of power (through its being accustomed to its secretion) to resist the attack of microbes, at first weak and then more and more virulent as introduced by the successive injections. When after having followed (as shown by observation) the nervous fibre going from the bitten spot to the cord, and thence to the brain, the infection germ reached the nerve cells of the cerebro-spinal axis, it found them fortified, as it were, against the attack, or that it could not do them any harm. In other words, immunity had been established. As demonstrating the fact that during anti-rabic inoculations such a course of events as that just described takes place, he brought forward the fact that his two assistants and himself all experienced during the inoculations a series of phenomena indicating that certain departments of the nervous system were stimulated into special activity by some unusual excitement.

During the time Dr. Gibier was taking the inoculations, and for a few days afterward, he observed a greater activity of the salivary glands than normal. Several times a day he felt the saliva welling into his mouth in such quantities that it became filled, and he was obliged to eject it. This symptom, which was also noted in the case of his assistants, was evidently a sign of excitation of the medulla oblongata. He recalled that in 1884 he had observed that polyuria was a frequent symptom in rabbits inoculated with the virus of hydrophobia. During the last week of the treatment and the week following he felt a certain heaviness of the head and an inability to work. This was also the case with his two assistants; but in them there were additional symptoms. Thus, on the fifth day, when inoculated with the marrow of the sixth day, one of them (M. Roger) complained of sudden pain in his right side, lasting about half an hour. On the eighth day (when inoculated with the matter of the fourth day) he experienced dizziness, and this lasted intermittently for fifteen days. On the twelfth day he felt pain in the lumbar region which extended as far as the right testicle. On the fourteenth day the vertigo was accompanied by buzzing in the ears, and he found walking difficult. Since the treatment, however, it was a fact that he had been relieved of a chronic dyspepsia, with pyrosis, and the bowels had also become more regular than before.

The other assistant (M. de Mouchy) was more affected with nervous troubles. From the second injection he felt pain in the nape of the neck. On the fifth day this pain spread into the brachial plexus, and after the

ninth inoculation some fulgurating pain was experienced in the region of the left crural nerve. On the twelfth day he suffered from a frontal cephalgia and an exacerbation of the pains at the nape of the neck. These symptoms continued for about fifteen days after the treatment had ended, and were accompanied by unusual sexual excitement, melancholy, preoccupation of mind, and vague pains in different parts of the body. The appetite, however, was always good.

Finally both the assistants were affected, on or about the fifteenth day following the last inoculation, with pains in the spots where the injections were made; and these pains were so acute as to suddenly awake them in the middle of the night. Dr. Gibier said he desired to call special attention to this circumstance, because in one case where an inoculated person died of hydrophobia, in spite of the treatment, the adversaries of the Pasteur method took advantage of a similar fact — that the patient had complained of pain at the spots where the injections were made — to claim that hydrophobia had been communicated to him by means of the inoculations. It could be seen, however, that these injections were capable of causing acute pain some time after they had been made without giving rise to hydrophobia. At the present time, nearly one month after the last inoculation, all three were in a perfect state of health.

In conclusion, he said that the sixteen persons who had thus far been inoculated at the New York Pasteur Institute were enjoying good health, while several domestic animals bitten by the same dogs which attacked several of these individuals had died of hydrophobia. A man bitten by one of these dogs, and not treated at the institute, had also died of the disease.

Dr. H. M. BIGGS said that, although almost from the very first he had felt confidence in the preventive efficacy of Pasteur's inoculations, it had always been a matter of surprise to him that in a disease associated with such extremely severe nervous phenomena as rabies, a system of inoculation against it which appeared so successful should be attended by such comparatively slight symptoms. During the past winter he had sent to Pasteur two children who had been bitten by a dog known to have rabies; and on the most careful inquiry, he could not learn that they had suffered from any symptoms of any importance whatever, except the local ones due to the irritation of the injections. The same was true in regard to a number of other inoculated patients whom he had had the opportunity of questioning.

In the case of the two children referred to, the history of rabies was perhaps the most complete that had ever been reported in this country. A dog with rabies bit two other dogs, one very severely and the other but slightly. The dog that was severely bitten was afterwards taken with the disease, and died with all the usual symptoms. The dog that was slightly bitten, was also sick for several days with all the characteristic symptoms of rabies; but it then recovered. Both these dogs were kept under close observation. Through the carelessness of an attendant the two children mentioned were allowed to come within reach of the animal that afterwards died of the disease, and they were both severely bitten by it. Furthermore, rabbits were inoculated with virus, not only from these two dogs, but from the first one, which had bitten them; and they all died in consequence. The children were treated by the Pasteur inoculations in Paris dur-

ing January last, and at the present time they are in excellent health.

Dr. GIBIER said that the case of the dog mentioned by Dr. Biggs, which had recovered after having had all the characteristic symptoms, was by no means an isolated one, as he himself had known of at least ten instances of recovery in dogs. While in dogs, however, it was the exception that recovery took place, in other animals, and especially birds, this was the rule. Thus chickens, for instance, very frequently recovered from the disease.

Recent Literature.

Surgical Bacteriology. By NICHOLAS SENN, M.D., Ph.D., Professor of the Principles of Surgery and Surgical Pathology, Rush Medical College, Chicago, Ill. Cloth, pages 270. Thirteen colored plates. Philadelphia: Lea Brothers & Co. 1889.

This volume is a reprint of the paper read by its author at the annual meeting of the American Surgical Association in September, 1888, under the title of "The Relation of Micro-organisms to Injuries and Surgical Diseases." Bacteriology has revolutionized surgical pathology, hence its importance to the science and practice of modern surgery. The first sixty-six pages treat of general subjects, namely, the hereditary transmission of microbial disease; the existence of pathogenic micro-organisms in the healthy body; sources of infection; microbial localization; elimination; and antagonism. Then follow the chapters on inflammation, suppuration, gangrene, septicemia, actinomycosis, gonorrhoea, and finally syphilis. The book concludes with a chapter on the alleged microbial origin of tumors.

The object of the writer has been to present his subjects as concisely as possible, and at the same time to omit nothing that is essential to a fair knowledge of it. A difficult task, considering the mass of literature published during the past few years. There has been such extended investigation and so much careful study in this important department of medicine; so much has been written, and opinions have undergone such radical changes during this time, that the active surgeon will gladly welcome a review which will give him, in a concise form, the actual results obtained by bacteriologists. The book is such a *résumé*.

It is a neatly printed, well-arranged volume, and is well illustrated by plates, mostly colored, which are reproductions from the "Lehrbuch der pathologischen Anatomie" of Professor Klebs.

The Principles and Practice of Surgery. By JOHN ASHWURST, Jr., M.D., Barton Professor of Surgery and Professor of Clinical Surgery in the University of Pennsylvania, etc. Fifth edition, enlarged and thoroughly revised, with 642 illustrations. Sheep, pages 1148. Philadelphia: Lea Brothers & Co.

The author's preface declares the object of this work to be to furnish in as concise a manner as may be compatible with clearness, condensed but comprehensive description of the modes of practice employed in modern surgery. Also the principles on which these modes of practice depend. The new edition resembles closely in its general arrangement its predecessors. The additions are estimated at about one-

eleventh of the last edition, and consist of new subject matter, with numerous illustrations. The chapter on Diseases of the Eye is by Dr. George E. Schweinitz. That on Diseases of the Ear by Dr. B. A. Randall. Both have been thoroughly revised. The remainder of the work has been done by Professor Ashhurst himself. The book is a valuable one, and is well arranged; but so encyclopedic a field cannot be satisfactorily condensed into a single volume. A book so written becomes a mere dictionary or manual, and is inferior to the excellent treatises (now in the hands of the profession), which treat solely of special subjects. It is a book adapted to the use of the medical student, rather than the hospital or general surgeon. Aside from the above criticism the volume excites only commendation. It is remarkable how much valuable information is condensed into and lies hidden in its pages.

A Treatise on Orthopedic Surgery. By EDWARD H. BRADFORD, M.D., and ROBERT W. LOVETT, M.D. New York: William Wood & Co. 1890.

A clear and thorough exposition of modern views and methods in the mechanical and surgical treatment of deforming diseases has long been a desideratum. Orthopedic surgery has made great advances in the past decade, and until the appearance of this work, the student or busy practitioner was obliged to hunt through pamphlets and medical journals to learn the latest and best treatment of diseases of this sort. In the present work this want is admirably supplied.

The writers have properly included in this treatise a consideration of many diseases of bones and joints which are usually not dealt with in the earlier works on orthopedics, but which require the skilful use of surgical apparatus for their successful treatment, and which, therefore, so often fall into the hands of orthopedic surgeons. It is also of interest to learn from authors familiar with the resources of mechanical treatment, a statement of the conditions under which the conservative methods must be assisted by surgical interference.

The chapters on Pott's disease of the spine, hip disease and diseases of the knee-joint cannot fail to be of interest to the general surgeon, and he will here find the most advanced, often original, ideas for their mechanical treatment.

The descriptions of apparatus and of operative procedures are precise and easily understood and are further made clear by abundant wood-cuts.

It would be well if all parents and school teachers could read the chapter on lateral curvature of the spine. They would here find the mechanism by which this most distressing deformity is brought about discussed at full length and the method of its prevention thoroughly treated. The nature of the gymnastic exercises which correct the tendency to this deformity is also explained, and the principles here laid down should be thoroughly mastered by every school principal who has the physical well-being of his pupils at heart.

The Boston Children's Hospital is a comparatively young institution, and this book produced by two members of its staff is a signal proof of the activity within its walls.

Hygiene of Childhood: Suggestions for the Care of Children after the Period of Infancy to the Completion of Puberty. By FRANCIS H. RANKIN, M.D., President of the Newport Medical Society, Member

of the Newport Board of Health, Fellow of the Rhode Island Medical Society, etc. New York: D. Appleton & Co. 1890.

Very few words are needed, beyond giving the headings of the chapters, in reviewing this admirable little book on the hygiene of childhood. No fault can be found from the beginning to the end of a work which is the best of its kind which has as yet appeared in medical literature. It is in every sense scientific, practical and concise, and can safely be put in the hands of all classes, professional or non-professional, which in itself indicates an unusually thoughtful and well-written book. In the space of one hundred and forty pages it covers sufficiently, without saying too much, such subjects as Dietary during Childhood, Protection of the Body, Importance of Pure Air, Exercise, Sleep, Regularity of the Bowels, Care of the Skin, Education, School Hygiene, Discipline and Puberty.

Dr. Rankin is to be congratulated on his simple rendering of a subject which other writers have failed to make simple, and therefore have not succeeded in producing a work suitable for the general public.

Outlines of Practical Histology. By WILLIAM STORLING. 12mo, pages xiv, 339, with 344 illustrations. Philadelphia: P. Blakiston, Son & Co. 1890.

This text-book is very good indeed, and will undoubtedly be widely used in histological laboratories and by medical students. It gives a very sensible and judicious account of the working materials of the histologist, and offers the student reliable advice as to microscopes, microtomes, reagents, etc. The greater part of the book is occupied by a series of chapters describing the tissues and organs. The descriptions are admirably drawn up, being concise, clear, and sufficiently exhaustive, with a few exceptions; each chapter also contains a goodly number of special directions for making illustrative preparations, a large and well-chosen assortment of which is figured in the text. It will thus be seen that in plan the work does not differ from other students' manuals of histology, but the plan is so well executed that we may accept the book as the best we have in English. It contains, however, more than the ordinary student of medicine requires, not in the way of description, but in very numerous special directions for making preparations. These, however, greatly increase the usefulness of the book in the laboratory and for more advanced workers.

As a defect we must consider the omission of an adequate account of the uterus — what is given is decidedly of a perfunctory character — nor is the history of the spermatozoa given up to the present state of our knowledge. In the chapter on striated muscle we miss references to the protoplasmatic reticulum which determines the muscular structure, and to the branching of the fibres and their anastomoses. These deficiencies, however, still leave the book full of merit. There remains a general criticism of a more serious character. The work is purely descriptive; there is no attempt to teach morphological principles, nor to give the student insight into the laws of cellular differentiation. This is, perhaps, the province of the embryologist, nevertheless, we believe that making histogenesis the basis of instruction renders the study of histology a matter of understanding, and renders it more interesting, accessible and valuable to the student than is possible by pursuing the duller methods of descriptive anatomy.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, AUGUST 21, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 28 Washington Street, Boston.

All letters concerning business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made, by money-order, draft or registered letter, payable to

DAMREL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE DIET OF HOT WEATHER.

The daily losses of the economy have been estimated at a mean of 20 grammes of nitrogen, 310 of carbon, and 30 of salts. To supply this waste, a quantity of nourishment is needed which may be roughly represented by 1,000 grammes of bread, 300 grammes of meat, and two ounces of butter or some other fat. Making all due allowance for differences in constitution, weight, sex, occupation, etc., a healthy man of average weight cannot vary much from this standard, in any season, without detriment.

The larger part of the hydro-carbon ingested is utilized in maintaining the heat of the body, and, according to many of our best physiologists, in supplying muscular force. The temperature of the blood must be kept constantly at about $98\frac{1}{3}^{\circ}$ of the Fahrenheit scale, and this internal heat must have its source in the metabolism of food and tissue. The same amount of muscular work necessitates the same expenditure of substance, whatever be the climate or season, so that the daily quantity of food needed to make good the organic wastes must always be nearly a constant quantity. There must be a due proportion of albuminoids, carbo-hydrates and fats.

And yet there are considerations which go to show that, in summer, and especially in the hottest period of summer, a minimum rather than a maximum quantity of food is required. The argument is based rather on experience than on positive scientific experimentation. That organic changes take place much more rapidly in cold weather than in hot, that a greater abundance of food is demanded, and that digestion and assimilation are more active in cold weather, are truisms of experience. Sir John Ross, Sir William Parry, Sir George Simpson, Lieutenant Greely and others have testified to the large amount of food consumed by dwellers in the arctic regions. "He who is well fed," says Sir John Ross, "resists cold better than the man who is stinted. In every expedition to the polar region, . . . the quantity of food should be increased, be that as inconvenient as it may. It would be very desirable,

indeed, if the men could acquire the taste for Greenland food, since all experience has shown that the large use of oil and fat meats is the true secret of life in these frozen countries."

But if appetite is enhanced in cold regions and in cold weather, and if an excess of carbo-hydrates and fats is demanded, it is a matter of common experience that, in tropical climates and in the hot season of temperate climates, the appetite flags, and digestion is retarded. People turn from the roast meats, the rich puddings and pastries, with disrelish or disgust, and demand some simpler dish — a little ripe fruit, with bread, a little lean meat and some plain vegetables, an ice-cream, a custard, a glass of milk.

But the lessened demand for food coincides with a relatively feeble condition of the digestive organs; so that in the midst of dog-day weather the abundant, rich meal of a cold winter day would be laboriously and imperfectly, if at all, digested. It is true that many persons with naturally robust stomachs insist on continuing into summer the full dietary of winter, and in pampering by various condiments and pickles — if not by claret, sherry and "bitters" — a faltering appetite. If speedy retribution, in the shape of indigestion, does not follow, such gourmands are likely later to suffer condign punishment in the form of dyspepsia, gout, plethora or polysarcia.

It is the part of true wisdom and common sense to practise moderation in regard to eating and drinking, of course, at all times, but especially in hot weather. Enough should be ingested to make good the losses — the organism must have its twenty grammes of nitrogen and its three hundred of carbon, and a good surplus may be allowed; but not much extra carbon is required to keep the internal temperature in equilibrium with the external, and tissue metabolism is certainly less active than in cold weather. Nature seems at this season to give a craving for fruits; and these certainly, when ripe, seem to be salutary, by their acids being "deobstruent" and refrigerant, and by their pulp and cellulose antagonizing constipation. The vegetables of the season, if eaten sparingly, ought to be unobjectionable; unfortunately they are often devoured before they are sufficiently mature or sufficiently cooked, or they are eaten in excess, and gastric embarrassment, diarrhoea and enteritis result. Rice seems to answer the requirements of a light, wholesome diet, easily digested, and with milk nutritious enough for hot weather; this cereal, in fact, forms the staple dietary of tropical countries. Beans, if cooked with beef instead of pork, form a wholesome and nutritious dish for an occasional summer repast; and milk, eggs, custards, creams, stale bread and biscuits are all to be retained in the bill of fare of hot weather. A little lean meat or fish, once or twice a day, seems to be required, at least by Americans. Of course, it is very important that such meats should be absolutely fresh, for poisonous ptomaines soon form in hot weather.

After all that has been said, the kind of work done

must largely control the dietary. Our haymakers and farmers who work at this season on the salt marshes still retain, amid the glowing fervors of the August sun, the *dura messorum illia*, and few of the cautionary precepts above given are rigidly applicable to them.

THE BERLIN CONGRESS.

THE International Congress at Berlin seems, from all accounts, to have been a very successful affair, especially in point of numbers. Physicians were present from nearly every civilized nation of the globe. Even France was well represented. The presidency of Professor Virchow was a marked success. He had the respect of all, and was listened to with great attention. At the opening it was announced that seven hundred papers had been presented for consideration in the eighteen sections, and more were expected. Certainly this was a larger number than even an international congress could handle with advantage. Of the value of many of the papers there can be no question; but it is at least doubtful if all of them could be called "path breaking." It is intimated by at least one correspondent who writes to a prominent daily paper, that a congress that is constituted practically of any or all who choose to attend, cannot fail to contain many men whose self-adoration is their principal claim to prominence. There must be much truth in such a statement; but the names mentioned show that very prominent men—men whose names are known the world over, have taken an active part in the business of the congress. The opportunity to see and hear representatives from such widely-separated countries is certainly a great advantage, and it is but little to say that even if no distinct and particular advance should come from the congress, the mutual understanding brought about by personal contact tends to unify and consolidate the universal profession.

Of the American representation we have reason to be proud. Dr. John S. Billings was one of the honorary presidents, presided for a time over the second general session, and read an interesting paper before the section of Military Hygiene. Dr. H. C. Wood delivered an address on "Anesthesia" before the congress. These were probably our most prominent representatives from their official connection with the congress; but five to eight hundred Americans were present.

THE QUINCY DISASTER.

THE public has just been startled by the announcement of another railroad disaster, which has caused the death of near a score of people, and more or less seriously injured many more. The accident occurred about one o'clock Tuesday. The number of injured was evidently overestimated at first, and doctors were summoned in large numbers. Many who responded to the call did so at great personal inconvenience, and only to find that their services were no longer needed.

Humanity seems to have inspired all—doctors and laymen alike—who were near enough to be of service. Residents in the neighborhood opened their houses to the wounded, and sheltered the dead.

The new hospital at Quincy has been in existence less than six months but the donor of that institution may feel repaid already for his outlay. The hospital on that one day justified its being, standing ready with its beds and surgical appliances to receive those so grievously in want of all that surgical skill could do for them.

MEDICAL NOTES.

— American surgeons are not the only ones who are subject to malicious suits. It is encouraging to learn that, whereas some time ago a hospital surgeon at Liège was cast in heavy damages (10,000 francs), in consequence of the somewhat unsatisfactory result of an operation performed on a child, the ground of the action being, not that there had been any lack of care or skill, but that the operation had been performed without the consent of the child's father, the Court of Appeal has just heard the case and given its decision, which is contrary to that of the court below, so that the defendant has at last had judgment pronounced in his favor.

NEW YORK.

— The State Dairy Commission has begun a crusade against a new kind of milk adulteration that has recently been brought to its attention, and several arrests have already been made in New York and Brooklyn. Most of the offenders are city milk dealers, although some of them are farmers and dairymen themselves. The adulteration consists in the addition of a chemical compound in the form of a nearly tasteless white powder, the exact nature of which has not as yet been made public. This substance, which is known as "preservaline," appears to have the effect of keeping milk from turning sour, and it is used in the proportion of almost half an ounce to a gallon of milk. In this proportion it adds three-eighths of one per cent. to the twelve per cent. solid proportion of the milk; and this alone would constitute an adulteration. The matter having been referred to Dairy Commissioner J. K. Brown and Deputy Attorney General Maynard at Albany, they rendered a decision that the "preservaline" was deleterious to health and without doubt an adulteration in the eyes of the law. Dr. R. D. Clark, the chief chemist of the Dairy Commission, Professor E. G. Low, and other chemists have all declared the substance is unwholesome and, when used for any length of time, decidedly injurious.

— Dr. E. W. Thwing, of Brooklyn, has just returned from a trip to China, on which he started a year ago for the purpose of investigating the field for the establishment of an insane asylum. He found the need of such an institution most urgent, as there is nothing of the kind in the whole Chinese Empire, where dissection is prohibited by law, and the native physicians, under-

standing nothing of the structure and function of the brain, are totally ignorant of the intelligent treatment of mental disease. An effort is to be made to raise \$20,000 in this country, and also a considerable sum in Europe, and Mr. John G. Kerr, an American gentleman who has resided for many years in China, is at the head of the project. Dr. Thwing states that a very desirable site just outside the walls of the city of Canton, in an elevated and healthy locality is under consideration for the proposed asylum, and that the enterprise has been met with much favor by the foreign residents especially. It is only half a century since the first hospital of any kind was established in China (at Canton), and the money for this was mostly paid by the people of Western nations. The first money paid toward the new hospital for the insane came from Japan, where they already have such institutions for such patients as are able to pay about fifty cents a day. At present there is no insane asylum for the poor there, but he says that a movement has already been started to establish one.

— The water has now been turned off again from the new Croton Aqueduct for the purposes of inspection, and the long tunnel is consequently clear from end to end. This is the first time in more than a year that the great siphon through which the water is carried under the Harlem River, and which was completed at a comparatively early period, has been made use of. Its construction was the most difficult engineering feat in the aqueduct plans, and has commanded wide attention and much scientific interest. In other aqueduct work in New York and elsewhere, rivers have been crossed by overhead structures. The siphon reverses the traditional practise, and carries the water through a section of aqueduct 370 feet below mean tide and about 450 feet below the top of the Harlem River banks. The principle that water will seek its own level is applied here boldly and on a large scale, the plunge that the water takes on the main land to reach the underground level furnishing pressure sufficient to raise the water again after crossing to a level that insures a steady flow through the section of aqueduct situated on Manhattan Island. The diameter of the siphon section of the aqueduct is a little over ten feet, or about two feet less than that of the remainder of the structure.

— Dr. William N. Blakeman, for many years a well-known physician in New York, died August 10th, in the 86th year of his age. He suffered severely from the gripe last winter, and had never recovered from its effects. He was born in Roxbury, Conn., in 1805, and graduated from the medical department of Yale College in 1832. He then removed to New York, and for over fifty years was an active practitioner, greatly esteemed and respected. He retired from general work some four years since, but still did a certain amount of consulting practice. Dr. Blakeman was one of the founders of the New York Institution for the Blind and the New York Infant Asylum, and the Society for the Relief of Widows and Orphans of

Medical Men, and of the New York State and County Medical Associations.

— The Rev. Charles Loring Brace, whose name will forever be associated with the noble work of the Children's Aid Society, of which he was the founder and up to the time of his death the Secretary, died on August 11th, in Switzerland. The amount of good accomplished by this Society since its organization in 1853 is simply incalculable. Thus, it has established lodging-houses for boys and girls in various parts of the city, where over 200,000 children have found comfortable accommodations. It has placed more than 70,000 children in good homes in the country, many of whom have since grown up to be worthy citizens. In addition, it has maintained a number of industrial schools in the city, where thousands of children have been instructed in useful employments, and for the last few years it has had summer homes at the seashore for infants and sick children; besides keeping up a free medical service among the tenement population. In 1856, Mr. Brace was a delegate to the International Convention for Children's Charities in London, and in 1865 he carried out a special sanitary investigation in the cities of Great Britain.

Miscellany.

THE BERLIN WATER AND SEWAGE WORKS.

PROFESSOR VIRCHOW's address at the opening of the International Congress at Berlin was listened to with great interest, according to all reports. In welcoming the members of the Congress to Berlin he gave an interesting account of the city's water and sewerage work which we append.

“But perhaps you will permit me to single out at least one institution for which the city of Berlin is classic soil. I mean our sewerage system, in connection with the municipal water-supply on the one hand and with the irrigation fields on the other. What a change this has made in the whole aspect of our city only those can judge who saw its streets and squares, its houses and dwellings, twenty years ago. The means expended, however, may give a general idea of the magnitude of the work. The sewerage system of the city cost 42,500,000 marks (that is, shillings), the purchase of the irrigation estates 12,500,000; the expenditure for the construction of the drains and the preparation of the fields amounted up to the end of March, 1889, to 79,000,000 marks in all. The book value of the municipal waterworks amounted at the same time to far more than 39,000,000 marks, and new works are already projected, the first half of which is estimated at 20,000,000. That makes for these sanitary works alone an expenditure of 138,000,000 marks. It cost hard struggles before the representatives of the city undertook these great enterprises: investigations of all the questions involved, lasting for years, went before; but at last the citizens of their own free conviction took their resolution, and adhered to it, even when the official authorities took a contrary view, and prophets of evil grew like mushrooms out of the earth. Thus Berlin has become a clean, a healthy, perhaps one may even say

in a certain sense, a beautiful city. Now this method of cleansing a city was no invention of ours. Many other cities had preceded us. Great waterworks were built even in remote antiquity.

"We do not claim that our works should be recognized as the best or as the only good ones. Altered circumstances always demand another solution. But what we wish to show you, and what we especially invite you to inspect, is the completeness and harmony of the arrangements which we have made. Nowhere in the world have such large tracts of land ever been used only for the purpose of cleansing the sewage waters of a city. Our irrigation fields comprise an area of 7,614 hectares. They form two large pretty well connected territories, one in the north, the other in the south of the city. In the year 1888-89 they yielded a surplus of 238,000 marks over the working expenses. You will convince yourselves that it is possible to meet Liebig's old demand that the soil, the vegetable world, or, let us say, agriculture, shall receive back what has been received from it, and even a little more. Not, indeed, the agriculturists, for though we do give sewage to some owners, it has been found necessary, for the sake of complete and constant purification, to keep the agricultural management in our own hands. Thus our city has become in a surprising degree, considering the modern division of labor, not only a great landowner but also an agricultural manager. In this way also certain possibilities have resulted which belong to the social political province, and which may probably be still further extended in course of time. The workmen on the irrigation fields are largely drawn from the city workhouse; in time they are converted from vagabonds into able workmen, earning money. The old mansions on some of these estates have been transformed into convalescent homes. Thus, without preconceived plan, the whole is developing itself more and more, on the basis of progressive experience, into a system of economic exchange of high social importance between city and country.

"Forgive me, honored Sirs, this somewhat long digression on a single group of municipal institutions. In importance, however, it far transcends all the other individual establishments and arrangements which you may study. It is, at the same time, the one which can teach more than the others how much the firm will and the cautious action of an independent community, testing step by step, and then, after thorough testing, going resolutely forward, are able to do in fulfilling the largest demands of science. And you will learn from them that almost all the great establishments which will be shown you were erected at a time when, in the opinion of some, Germany was occupied with nothing but preparation for new wars. No, gentlemen, we are honest adherents of peace. We know that peace nourishes and dissension destroys. We wish to live in concord with all the world, in order to pursue the tasks of science and the aims of humanity undisturbed, and in our own way."

OBSTETRIC HERNIA: THEIR CAUSES, SYMPTOMS AND TREATMENT.

The following is an abstract of a paper by Thomas More Madden, M.D., F.R.C.S.(Ed.), prepared for the British Medical Association:

"Ovarian hernia are amongst the most neglected, although clinically they should be included amongst the most important, of the troubles that come before us in gynecological practice. In the great majority of cases they occur downwards into Douglas's space, and in such instances the left ovary is that most frequently displaced. The next in point of frequency of these hernia are those occurring in the inguinal regions where they are either found above Poupart's ligament or as more commonly the case, follow the course of the canal of Nuck downwards and forwards, and so present in the labia where they may be readily recognized. In the former or directly downward variety of displacement, the ovary may be discovered on vaginal examination in the recto vaginal fossa as a small, oval-shaped, firm, elastic and highly sensitive tumor, bulging forward into the post-cervical *cul-de-sac*. In the larger number of cases ovarian hernia, especially those in Douglas's space, result from the *vis a tergo* of abdominal or uterine tumors, or from the tension on the appendages occasioned by displacements of the uterus.

"*Diagnosis.*—Until recently these hernia when inguinal were very generally compounded with enlarged glands; when labial with other tumors in that situation; and when downwards with pelvic abscess and hematocoele. Or, as often happens, they are mistaken for the retroflexed fundus uteri, and the patient suffering from an ovarian prolapse is vainly treated for a non-existent retroflexion or retroversion of the uterus. There can now be no excuse for such errors. The sudden occurrence of the tumor, its physical character, the peculiar dull sickening pain, and the extreme tenderness and nausea manifest on examination are sufficient to enable a correct diagnosis to be made by any competent gynecologist.

"*Treatment.*—Where the ovarian hernia takes place through either of the abdominal rings or downwards into Douglas's space, it may in some instances be reduced, as any other hernia similar situated. In the majority of cases, however, such hernia are irreducible when discovered, and must either be supported in the former case by applying a hollow truss whilst in the latter case the prolapsed ovary must be replaced if possible and kept in position with a peculiar form of pessary, exhibited, specially devised by Dr. More Madden for the purpose, or failing this, if the symptoms be urgent the ovary must in some cases be removed."

The foregoing views are illustrated by the details of several instances of ovarian hernia, exemplifying the clinical history and treatment of such cases.

OBITUARY. HERMAN E. DAVIDSON, M.D.

Dr. Herman E. Davidson who died of angina pectoris, at his summer residence in North East Harbor, Mt. Desert, Sunday, August 10, 1890, was born in Potham, N. H., August 10, 1815. At the age of twelve he entered the academy at Derry, N. H., and after two years went to the academy at Exeter, N. H., where he fitted for Harvard College, entering at the age of seventeen in the year 1832 and graduating in 1836. The following two years he studied medicine in the office of Dr. W. J. Walker at Charlestown, Mass., where his father's family were then living, and at the same time attended the lectures at the Harvard Medical School, taking his degree in 1840.

In January, 1841, he settled in Apalachicola, Florida, where he practiced medicine for about eight months, after which he returned to his father's residence in Charlestown. In September, 1842, he settled in Gloucester where he became a leading physician, and as the town grew to a city, he became identified with many of its institutions.

August 9, 1859, he married Mrs. Sarah M. Chamberlain in Boston, and they continued to live in Gloucester until 1878 (having travelled from 1872 to 1875 abroad), when he permanently left Gloucester on account of his wife's health to reside in the milder climates of this country. She died in Washington, D. C., May 16, 1880.

From 1880 to 1884 he resided in the United States, except one winter spent in Bermuda, when he again visited Europe, living at Paris, Caunes, London and the Isle of Jersey in England, and passing one winter in the Madeira Islands on account of the health of his two daughters. In 1889, he returned to Boston staying until the winter when he went to Bermuda and remained there until the summer of 1890. On his return to Boston he leased a furnished house at North East Harbor and was residing there with his two daughters at the time of his death.

During his residence in Gloucester he built up a large practice. With that calm and confident demeanor peculiar to himself, always equal to any emergency, unattended with the slightest vanity, he drew around him a large number of admirers who considered it a pleasure and honor to possess the acquaintance of such a man.

In the pursuit of his profession and those subjects in which he was interested, it was natural for him to be continually considering how he might improve the existing methods and devices.

Among the many improvements brought into use by him was the Davidson Bulb Syringe, now universally in use invented and first used by him in his practice some thirty-four years ago, it being the first bulb syringe ever made. Another was a meat press, simple and thorough. Still another invention was called "Davidson's Method in Ichthytaxidermy," or the mounting of fish for use in the study of natural history. So admirable was this peculiar method that many examples of it have been prepared by him or others who have been instructed by him, and placed in the natural history museums both in this country and abroad at the request of these institutions.

He was a person well informed in general literature and scientific subjects, and especially interested him, and whilst a resident of Gloucester he occupied many prominent positions of honor and trust.

In Gloucester he was a member of the school committee for several years, the first president of the Cape Ann Scientific and Literary Association, vice-president of the Cape Ann Horticultural Society, one of the incorporators of the Oak Grove Cemetery and a member of the Board of Trustees until his removal from the city.

Beloved by many and endeared to all with whom he was brought in contact both in his family circle and elsewhere from his many kindly acts, his death has caused a sorrow which time only can efface.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 9, 1890.

Cities.	Estimated Population for 1890.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,782; under five years of age 1,504: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 774, consumption 247, acute lung diseases 131, diarrhoeal diseases 62, typhoid fever 93, diphtheria and croup 53, whooping-cough 41, measles 14, cerebro-spinal meningitis 14, scarlet fever 12, malarial fever 9, erysipelas 5, puerperal fever 4.

From whooping-cough, New York 13, Philadelphia 10, Chicago 8, Salem 4, Lawrence 2, Baltimore, Portland, Cambridge and Taunton 1 each. From measles, New York 10, Chicago and Boston 1 each. From cerebro-spinal meningitis, Clinton 4, Washington 3, New York 2, Philadelphia, Baltimore, Boston, Lowell and Quincy 1 each. From scarlet fever, New York 4, Philadelphia 3, Chicago 2, Boston, Springfield and Pittsfield 1

each. From malarial fevers, New York 5, Baltimore 3, Charles-ton 1. From erysipelas, New York 3, Chicago 2. From puerperal fever, Chicago 3 and Baltimore 1.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending July 26th, the death-rate was 17.6: deaths reported 3,276: infants under one year 957, acute diseases of the respiratory organs (London) 185, diarrhoea 208, measles 142, whooping-cough 100, scarlet fever 55, diphtheria 39, fever 16.

The death-rate ranged from 24.6 in Newcastle-on-Tyne to 11.7 in Portsmouth, Birmingham 16.9, Bradford 17.8, Hull 14.4, Leeds 17.3, Leicester 16.6, Liverpool 21.0, London 16.7, Nottingham 16.2, Sheffield 19.3, Sunderland 19.9.

In Edinburgh 21.0, Glasgow 23.6, Dublin 20.

The meteorological record for the week ending Aug. 9, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.		Relative Humidity.		Direction of Wind.	Velocity of Wind.	State of Weather.*	Rainfall.
		Daily Mean.	Daily Mean.	Maximum.	Minimum.				
Saturday, Aug. 9, 1890.									
Sunday... 3	30.18	71.0	82.0	61.0	83	84	83.0	S.	S.W.
Monday... 4	30.12	73.0	80.0	69.0	84	75	80.0	S.W.	S.W.
Tuesday... 5	30.16	80.0	89.0	72.0	71	78	75.0	S.	S.

*O., cloudy; C., clear; F., fair; G., fog; H., hazy; S., smoky; R., rain; T., threatening; N., snow. † Indicates trace of rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 9, 1890, TO AUGUST 15, 1890.

By direction of the Acting Secretary of War, Captain WILLIAM STEPHENSON, assistant surgeon, now on duty at Columbus Barracks, Ohio, is assigned to temporary duty at Jefferson Barracks, Missouri, during the absence on leave of Major Daniel G. Caldwell, surgeon, and will report accordingly. On the return to duty of Major Caldwell, Captain Stephenson will rejoin his present station. S. O. 176, Par 2, A. G. O., Washington, D. C., 1890.

By direction of the Acting Secretary of War, leave of absence for one month and fifteen days, to take effect about August 15, 1890, is granted Major DANIEL G. CALDWELL, surgeon. S. O. 176, Par. 1, A. G. O., Washington, D. C., July 30, 1890.

By direction of the Secretary of War, the ordinary leave of absence granted Major JAMES P. KIMBALL, surgeon, in S. O. 152, July 1, 1890, from this office, is changed to leave of absence on surgeon's certificate of disability, with permission to leave the Division of the Missouri. Par. 7, S. O. 182, A. G. O., August 6, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 16, 1890.

P. S. WALES, medical director. Detached from Medical Examining Board and resume present duty at Museum of Hygiene.

H. E. AMES, passed assistant surgeon. Ordered as member of Medical Examining Board in addition to present duty.

J. S. SAYRE, passed assistant surgeon. Detached from Navy Yard, New York, and to the U. S. S. "Ranger."

J. H. NORTH, Jr., assistant surgeon. Ordered to the Navy Yard, New York.

GEORGE H. BARBER, assistant surgeon. Detached from the U. S. Receiving-Ship "Vermont" and to the "Pensacola."

L. L. VON WEDDEKIND, assistant surgeon. Detached from the "Pensacola" and to the "Vermont."

E. W. AUZAL, passed assistant surgeon. To temporary duty at Naval Academy to examine candidates.

A. B. PITTS, passed assistant surgeon. Detached from U. S. S. "Pinta" proceed home and wait orders.

E. P. STONE, passed assistant surgeon. Detached from the U. S. S. "Independence" and to the "Pinta."

J. M. WHITFIELD, assistant surgeon. Detached from the "Monitor" and to the Naval Hospital, Norfolk.

JOSEPH AYERS, surgeon. Ordered to Naval Academy to examine candidates for admission.

GEORGE H. BRIGHT, surgeon. Ordered to Naval Academy to examine candidates for admission.

GEORGE T. SMITH, assistant surgeon. Detached from Naval Hospital, Norfolk, and to the U. S. S. "Independence."

S. S. WHITE, passed assistant surgeon. Detached from Marine and to the Naval Rezendevous, San Francisco, Cal.

DEATH.

Dr. Charles Steele Thomson, the oldest living graduate of the Yale Medical College, died August 14th, at Hartford, Conn. He was ninety years old. He was in active practice in New Haven for nearly fifty years, retiring about seven years ago.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FROM JULY 26, 1890, TO AUGUST 12, 1890.

SAWTELLE, H. W., surgeon. Granted leave of absence for fifteen days. August 8, 1890.

WHEELER, W. A., passed assistant surgeon. Granted leave of absence for thirty days. August 5, 1890.

CARMICHAEL, D. A., passed assistant surgeon. Granted leave of absence for thirty days. August 2, 1890.

PECKHAM, C. T., passed assistant surgeon. Granted leave of absence for thirty days. July 28, 1890.

AMES, E. P. M., passed assistant surgeon. Granted leave of absence for fourteen days. August, 1890. To proceed to Shreveport, La., as inspector. August 5, 1890.

KALLOCH, F. C., passed assistant surgeon. Granted leave of absence for seven days. July, 1890.

PERRY, J. C., assistant surgeon. To proceed to Wilmington, N. C., for temporary duty. July 31, 1890.

SMITH, A. C., assistant surgeon. Granted leave of absence for thirty days. August 11, 1890.

YOUNG, G. B., assistant surgeon. Leaves of absence extended twenty days on account of sickness. August 2, 1890. Upon expiration of leave, to proceed to New Orleans, La., for temporary duty. August 8, 1890.

STIMPSON, W. G., assistant surgeon. When relieved at Buffalo, N. Y., to proceed to Norfolk, Va., for temporary duty. August 5, 1890.

SOCIETY NOTICE.

AMERICAN CLIMATOLOGICAL ASSOCIATION.—The annual meeting of the Association will be held in Denver, September 2 to 4, 1890. One-third of the time is expected to be given exclusively to the study of Colorado subjects, and after the three days' sessions, the visiting physicians are to be given an opportunity personally to investigate the mountain resorts, by a series of complimentary excursions.

The programme includes a great variety of papers.

BOOKS AND PAMPHLETS RECEIVED.

The New Treatment of Peritonitis. By Emory Lanphear, M.D., Kansas City, Mo. Reprint. 1890.

Tenth Annual Report of the State Board of Health of New York. Transmitted to the legislature February 20, 1890.

A New Operation for Prolapsus of the Anterior Vaginal Wall. By Andrew F. Currier, M.D., New York. Reprint. 1890.

Thirty-first Annual Announcement and Catalogue of the Hahnemann Medical College and Hospital, Chicago, Illinois. 1890-91.

Report on the Cause of the Recent Outbreak of Typhoid Fever in Waterbury. Made to the Connecticut State Board of Health. By Herbert E. Smith, M.D. 1890.

The Prison Question. A Theoretical and Philosophical Review of Some Matters relating to Crime, Punishment, Prisons, Reformation of Convicts, etc. Designed to show how society may protect itself against the disorderly elements, and check the rapid increase of the prison population. By Charles H. Reeve. Chicago: Knight and Leonard Co. 1890.

Address.**SOME EXTRA-MEDICAL MANIFESTATIONS
OF HYSTERIA.¹**

BY CHARLES F. WITTINGTON, M.D.

MR. PRESIDENT AND FELLOWS:—The position upon your programme to which you have assigned the annual address, after the dinner, is, I take it, an intimation that you do not desire a dissertation upon any of the weightier matters of technical professional interest. On the other hand, I cannot hope to strike that vein of elegant persiflage which was so richly opened at our last meeting. If your dinner this year lacks such a sparkling dessert as you had a year ago, you must find fault with those who arranged the *menu*.

After listening to the address of last year, in which the progressive decadence and present uselessness of our profession were so clearly shown, we all returned to our homes prepared, I doubt not, to assist in the speedy dissolution of this Society, and ready to seek some occupation which, however untried and humble, should at least be an honest means of gaining a livelihood. And yet, somehow or other, we still find ourselves working on, not utterly ashamed, in the old calling, and our Society at the close of another year is actually larger than ever before.

Supposing, after all, that our therapeutic creed has of late years had to be shortened; supposing we are less sure than we used to be of our actual ability to control morbid processes; may not a sifted remnant be more valuable than the heterogeneous mass, the refined metal than the bulky ore? The "medicine-men" of savage tribes, we are told, are accustomed, on the occurrence of a solar eclipse, to raise a tremendous din with their shrieks and the beating of their tom-toms in order to drive away the malign influence which has brought sudden darkness and terror to the face of nature. Soon the sun's rays return, the world is bright again, and thousands of dupes hasten to pay homage and reward to the men who, as they believe, have averted the eclipse. But as the people's knowledge increases they find out that the beating of the tom-toms did not drive away the eclipse. Is there then nothing left for the wise medicine-men to do? Surely they can say: "That was all a mistake. We didn't drive away the eclipse. It would have gone away just as quickly if we had kept still. But we are not altogether fools in this matter. We can predict the next eclipse; can tell you just when it is coming, where it will be visible; and, what is more important, we can assure the timid and panic-stricken among you that the shadow will certainly pass away, and can tell you the exact minute when it will do so."

In just the same way astrology and alchemy have died. But their successors, astronomy and chemistry, starting with more modest claims, have gone on to achievements far more wonderful than the pseudo-science of their predecessors ever dreamed of.

It is a habit, I believe, with medical anniversary speakers to dilate with some self-gratulation upon the advantages which may accrue (perhaps upon those which have accrued) to the public, — the vulgar, as I think Dr. Jacob Bigelow used to call them, from the educating influence of the medical profession. I, for one, do not feel so sure about that. We have given

them good advice, — lots of it. We tell them what is dietetically correct, and after they have seen us eat a certain amount of Welsh rabbit and plum pudding their ideas become confused. We give them "Emergency Lectures," and after we have explained the theory and practice of applying the tourniquet, we are appalled at being asked, as I once was by a policeman, if the "blood goes down one leg and comes up the other."

We have tried to explain to them the mysteries of medical etiquette, but they can't seem to understand why their sick or dying dear ones must be left to hours of unrelieved suffering because the proper formalities of an orderly consultation cannot be sooner complied with. Then the consultation itself, they seem to think, these people who pay for it, ought to add something to the knowledge of the case, or to its treatment, and not be always merely a formal patting on the back of the attendant physician. The real verdict "Diagnosis wrong, treatment wrong, but not worth while to change it now," would appear to them like the prophet's "Peace, Peace, when there is no Peace."

You remember Thackeray's old woman who goes to Tunbridge or to Bath with a letter from her doctor to a brother practitioner, containing, as she supposes, a detailed account of her symptoms. Led by the wish to luxuriate in a description of her malady couched in sonorous Latin terms, she most unjustifiably opens the letter and what she reads in this: "Keep the old cat six weeks and then send her back." And yet she, like the people of our own day, failed to see the benefits of medical counsel.

No, if I were to speak of the educating influence of the medical profession upon the laity, I should turn to a different class of subjects. For instance, I should point out that we owe the public an especial education in the matter of paying their bills, especially their doctor's bills. Some of us have been remiss in this duty, and it is time that we took it up for the patient's own good. If we allow them to think that the doctor's bill is to be deferred, as one old lady expressed it, till "after they have paid their honest debts," we shall allow them to form habits which may be fatal to their peace of conscience, and incidentally also to the peace of mind of our sons and successors. Early bills and prompt settlements is a good lesson in self-reliance and self-respect, worth the learning by every profession and every class in the community, who have not the misfortune to be necessary objects of charity. Let us help the public to learn it.

Another lesson that the public needs to be taught in its relation to our profession is the primary but much neglected one of *how to summon the doctor*. This lesson may be divided into two parts — the time and the manner. Night-calls, the bane of our profession, ought to be minimized, and a proper application of the extra tariff recognized for such service will do something to effect this. Of course they are sometimes necessary. Child-birth and other abdominal disturbances will occur by night, and no philosophy which their subjects can summon will brook long delay in getting medical aid. But there is a class of patients (and their power for evil has been enhanced by the fatal facility which the telephone gives of reaching the doctor without exposing a messenger to the night air) who are like Macbeth. They "murder sleep, the innocent sleep." They discover that they

¹ Annual Address delivered before the Norfolk District Medical Society, May, 1890.

are getting stout, or are growing gray, or have lost their appetite, or they find that their child has a mole or is bow-legged, and the poor doctor is dragged from bed to attend to what might have been done a little later or a good deal earlier.

Or again, these people, if they find night-work is expensive, will send for the doctor at odd times, the middle of the forenoon or the late afternoon, thus obliging him to retrace ground, perhaps, already covered, and preventing that orderly and labor-saving arrangement of his work which could have been made if the call had been sent, as it might perfectly well have been, early in the morning.

Then these persons need training as to how to have the call. They say, "Come to Mr. Smith's," when they ought to know that means nothing whatever to the doctor, who has various members of that abundant family on his books, and must, therefore, wait for further directions before he can respond. On the other hand, some messengers are quite too particular. They will not intrust their call to writing, but insist upon seeing the doctor himself. He is, perhaps, in the bath, or he has removed his professional garb in order to engage in some of those humbler domestic services to which his good wife invites his leisure hours. A caller is announced. The office-hour is over, but duty (and incidentally the prospect of pecuniary aggrandizement, greater than that attaching to the non-professional work in hand), cannot be neglected. He leaves his work half done — makes his toilet, changes his clothes, and finally sees his visitor, who merely wanted him to call around and see the baby. Perhaps, however, having got possession of the doctor, he details the facts in the case, all of which have to be gone over again when, an hour or two later, the visit is made.

But the most crying abuse connected with the sending for the doctor is the uncalled-for imperativeness of the message. Some people, after making up their minds that they want a doctor, can't get him soon enough. Their message always reads "come at once," or "come as soon as you possibly can." Occasionally I have found that this feature of the call was the uninspired work of the messenger, who thought it was a business-like way to couch his message. But often enough it is the fault of patients, who ought to know better. Perhaps they fall into it from their experience with the plumber or the carpenter, whom it is necessary to tell that he must come forthwith if you expect to get him a week hence. In cases of accident the community goes fairly wild. Messengers are sent in every direction, each to call all the doctors he can find, those who are in to come at once, and those who are out to come as soon as they return. Meantime the patient's friends decide to send him to the hospital, and his house becomes the rendezvous of constantly-arriving doctors, whose coming it never occurs to anybody to forestall.

Well, there is an old fable about the boy who cried "wolf" too often, and every doctor has on his list certain people to whose uniformly urgent calls he has learned to give a large discount.

The Medical Fetich — how many families are there who are without it? With some it is the string of amber beads which are to ward off croup. The horse-chestnut, carried in the pocket for rheumatism; or the discarded but still awe-inspiring carbon-tip from an electric light, containing what unknown stores of electricity and therefore life; the electric belt; the lustrous

finger-ring, another rheumatic prophylactic; the camphor-bag, which the mother hangs around her child's neck to keep off scarlet fever. These and scores of other amulets and charms we meet with everywhere. And can we laugh at them, when within the year our own profession has run after just such another fetich — the "elixir of life"?

Let us remember — those of us who were not born into medical families — how we ourselves once viewed some of these questions before we became of the number of the initiated. Probably we once believed that there was a specific remedy for every disease, which only needed to be taken early enough to conquer the disease, whatever it was. Possibly we have even thought it necessary to take medicine to keep well, and have resorted to spring bitters to "thin down the blood," like our flannels, to a degree adapted for summer wear. We may have received, if not given, wormwood tea (and it is more blessed to give than to receive), when the *corpus delicti* was not a tape-worm, but an error of diet — in fact, not a parasite, but an oversight.

How shall we deal with these vagaries of the public? It is very doubtful if anything is to be gained by scotching them openly. People will either cling to their original fetiches, or at most, transfer their allegiance to others of like character. Moreover, they will very likely quote the well-worn adage of Hamlet that "there are more things in heaven and earth than are dreamt of in our philosophy." And this we cannot gainsay. On the other hand, if we keep silence and allow what is obviously harmless in domestic therapeutics to be continued, we shall find ourselves publicly quoted as sanctioning the most absurd of the old wives' fables.

Solomon the Wise displayed his judgment in the way he dealt with this subject. He has left us two maxims bearing upon it, one or the other of which I think we shall do well to follow. The first is, "Answer not a fool according to his folly"; and the second is, "Answer a fool according to his folly." Both these rules have their appropriate application, and between them, they seem to cover quite fully a somewhat delicate subject.

There is one subject, ladies and gentlemen, upon which, if you will allow me for the remainder of my time to turn into a somewhat more serious vein, I should like to say a few words. It concerns one element of popular weakness which is rather far-reaching in its effects, and for which our profession, I believe, has from its training an especial opportunity, and therefore an especial duty to correct. It is what I may call, for a short term, *Extra-Medical Hysteria*.

As physicians we are all familiar with a certain group of symptoms which we know by the name hysteria. We are told that it may simulate any known disease, but in the farrago of symptoms, motor, sensory and psychical, to which it gives rise, we recognize as a general underlying condition, a feebleness of the will-power and of those cerebral impulses whose office it is in the well-balanced economy to dominate simple reflex actions. We admit the powerlessness of drugs (except in the most general way) to combat this condition, and we know full well when called to the care of such a case that it means much more than writing prescriptions; that besides reinforcing a weak physical organization, we are to have the far harder task of strength-

ening the feeble powers of self-dependence and moral purpose, of confirming a self-distrustful and halting will.

To the student of social conditions at the present day, especially if he be a physician, it will, I think, appear evident that mental and moral states very similar to those just referred to have an existence and an application outside the realm of disease, and that they may, in various departments of human activity, have as deplorable an influence as they have when they expend themselves on an individual organism.

Mrs. Helen Hunt Jackson, in one of her charming volumes, has a chapter entitled "Hysteria in Literature," in which she refers to the ill-balanced emotionalism of much that goes under the name of literature. In its more rampant and effusive form it is to be found in the dime-novels and novellets, the "Flags" and "Blades" and "Gazettes" among newspapers, with which children of the more neglected classes openly, and those of the more favored classes secretly regale themselves. It shows itself, like an indecent exposure of the person, in the works of the "realistic" school of novelists. In a somewhat less glaring form it is seen in novels and poems where it takes the form not of over-wrought and sensational plot, but of morbid mental introspections and dissections, of wild vaporings, of yearnings for no one knows what. If I were to name an instance of this kind of hysterical novel (which is perhaps unwise, as it is always safer to speak in the abstract than in the concrete) I might mention Amélie Rives's "The Quick and the Dead."

A word of qualification is here in place. Sentiment is not a sign of hysteria; sentimentality is. The former is, as it should be, controlled by reason and common sense; the latter is devoid of any such control. So the most complete type of womanhood has sentiment, which may show itself in the strongest evidences of affection. But it is the ill-balanced, the hysterical, whose emotions run away with her. So all that has been said regarding literature has nothing to do with poetry, or any other expression of the best and truest sentiment, provided always it has a firm foundation in reasonableness and self-restraint. "Sense and sensibility is a strong combination." It is like the mountain, with its base on earth, and its apex in the skies. Sensibility alone is like the balloon which may, indeed, rival the mountain in elevation, but whose equilibrium is unsteady, its course erratic and brief.

One form of hysterical literature is to be found in a certain class of metropolitan journals, generally I fear those which, if one may believe their claims, enjoy "absolutely the largest circulation of any daily paper." What a fine frenzy such a journal works itself into over a murder, especially if that crime be conjoined with something worse. Its headlines, equally extravagant in words, in type and in ink, are for all the world like the *grands mouvements* of a hystero-epileptic. They are the scenic and spectacular element which catches the eye, and serves to usher in the other phases of the seizure. These latter are, in hysterical journalism, an exposure of the most private and personal facts in the history of the persons involved, and of their families. The minute circumstances of the killing; the revelations of the autopsy; a cursory sketch, if possible with photographic cuts, of the female friends of the victim, in an attempt to hit upon the "woman in the case." Failing a good murder, a pungent divorce-suit, or a church scandal furnishes a very good opportunity for a similar display, — sometimes a better

one because of the sexual color which it imparts to the scene. Through it all, judgment, taste, veracity and decency are all subordinated to the desire to produce a sensation.

The reporter knows that his prospects for advancement depend less on careful conscientious work than on the faculty of writing "vivid," that is, over-wrought pictures of harrowing and exciting scenes. Surely such journalism as will stoop to key-holes will sell for money the words uttered in the freedom of a fireside conversation, will invade the sanctities of domestic life, will send its minions to dog the honeymoon of the chief magistrate of the nation, — such journalism is given up to emotionality without control. Its "sensationalism" is essentially hysteria.

The hysterical drama is a conspicuous illustration of the principal of which we have been speaking. The "old-fashioned melodrama" with its abducted heir, its stolen diamonds, its forged will, its smooth rich villain, its betrayed girl, its rightful heir, preserved by a faithful servant through countless perils, its agonizing situations eked out by tremulous music from the violins, all this is unnatural, unreal, ill-balanced, hysterical. So, though less objectionable because less maudlin, is the furious fun of the extravaganza. But even in the dramatic classics one cannot feel safe, for the "emotional" actress can "tear a passion to tatters" even if the passion is that of Shakespeare, and good comedy can very easily be run into farce to please those groundlings who, if they cannot have their ears split or their eyes pumped, must have horse-play enough to tickle their obtuse diaphragms.

It is almost exactly two centuries since the social fabric of New England was almost disrupted by the consequences of a most terrible manifestation of hysteria, the witchcraft delusion. Doubtless there was also, in the phrenology of the present current medical fad, something of hypnotic suggestion in the testimony of the supposed victims, and in the confessions of the supposed witches: but the experiences of the bewitched, and indeed the whole mental state of the public, represented one great storm of epidemic hysteria, which the few calm and steadfast minds were powerless to withstand. Cotton Mather's "Wonders of the Invisible World" contains what are to us life-like pictures of this *status hystericus*. Let me quote one among many such examples from the testimony of a witness at the trial of Susannah Martin.

"William Brown testified, that Heaven having blessed him with a most Pious and Prudent Wife, this wife of his, one day met with *Susannah Martin*: but when she approach'd just unto her, *Martin* vanished out of sight and left her extremely affrighted. After which time the said *Martin* often appear'd unto her, giving her no little trouble: and when she did come she was visited with Birds that sorely pick'd and prick'd her; and sometimes a Bunch, like a Pullet's Egg would rise in her throat, ready to choke her till she cry'd out, *Witch, you shan't choke me!* While this good woman was in this extremity the church appointed a Day of Prayer in her behalf: whereupon her trouble ceased: she saw not *Martin* as formerly, and the church instead of their Fast gave Thanks for her deliverance." The recovery was not permanent however, and Mather concludes: "Soon after she fell into a strange kind of distemper, and became horribly frantic and incapable of any reasonable Action; the Physicians declaring that her Distemper was preter-

natural and that some Devil had certainly bewitched her : and in that condition she now remained."

Again unconscious evidence is given to the hysterical nature of the symptoms in a woman named Whetford, who having testified in the trial of Bridget Bishop and been threatened by Bishop was, as was said, pulled out of bed in the night by apparitions and carried to the sea to drown: "but she calling upon God, they left her, though not without expressions of their Fury. From that very time," says Mather, "this poor Whetford was utterly spoilt and grew a Tempted, Froward, Crazed sort of a Woman: a vexation to herself and all about her; and many ways unreasonable."

Religion is a domain in which Hysteria has made havoc. Some of the devotees of Islamism and Brahminism are notable instances in point. The whirling dervishes and the fakirs of the East need only to be mentioned. The latter are to be seen at this day in India with their arms fixed in rigid attitudes, their nails grown till they have transfixed the palms of their hands. Others we are told, tie hands and feet together and thus roll end over end for thousands of miles. Nor has Christianity been exempt from similar scenes. The lives of the medieval saints are full of instances. St. Anthony's conflicts, for example, with demons who in the guise of voluptuous women continually beset him, have been a favorite subject for the artist's brush. Indeed, the monastic life in all religions, with its contempt for physical needs, its prolonged vigils, its introspection and its atmosphere of mysticism, has been especially favorable to the development of hysteria; but we cannot congratulate ourselves that the religion of the present day is exempt from it. The scenes in some so-called revivalistic gatherings of the South and West, which have been well described for medical readers by Dr. D. W. Yandell and others, illustrate a marked form of convulsive hysteria, in which hundreds of the so-called "jerkers," influenced by pseudo-religious frenzy and the contagion of one another's example, went through all sorts of gyrations, dashing to the ground, writhing and bounding from place to place. Can we truly say that some exhibitions a good deal nearer home, given by the Salvation Army and under other auspices, have been altogether free of the same mental states, even if the physical contortions have been somewhat less marked? The hysterical mind, if it be turned toward religion, finds the "patient continuance in well-doing" a tame affair compared with the exhilaration obtained, according to the ecclesiastical affiliation of the individual, either by revivalistic excitements, mystical musings or ritualistic rhapsodies. And this is said without any wish to condemn the temperate employment of any of these aids to religious life.

Practical reforms and charities are hampered by the hysterical or emotional spirit in their supporters. It is admitted by all thoughtful persons that the charity which is most permanently beneficial, is not that which bestows outright upon its recipients but which puts it within the power of the poor and unfortunate to secure what they need for themselves by their own effort. While outright gifts of money and supplies doubtless require at times to be given and should not then be withheld, they should be looked upon as opiates in neuralgia, as palliatives merely, useful in their place and for a short time, but liable to be called for again and again, and able to cause great mischief if used too much. The hysterical mind, with a weak good-nature,

is unwisely altruistic. It gives to the street-beggar without taking the trouble to investigate his deserts. It is constantly getting up new societies, if not for the sending of top-boots to the cannibals, for almost equally quixotic and emotional objects. It delights in agencies and organizations which publish affecting reports, but it is not apt to be the almoner of its own charity, and it forgets that the personal contact of giving with receiver is the best channel for the transmission of good deeds. The filaments which should transmit helpfulness from man to man cannot be twisted together in the person of any society "agent."

Entrenched abuses are not permanently swept away by hysterical reformers. An enthusiast may do a great work, but his enthusiasm must be well ballasted by common sense if it is to override all obstacles and lead to permanent results. The women of Ohio can never overcome the curse of intemperance by raiding saloons and smashing whiskey-barrels. The work of the emancipation of the slave was far surer and safer in the hands of Abraham Lincoln than it ever could have been in those of John Brown, of Osawatomie.

Did time permit, we might, I think, find in art, in politics, and in other departments of human progress, further evidence, which indeed will suggest itself to your own minds, of the unfortunate influence produced by the hysterical or emotional element in human nature, if unchastened by self-restraint and common sense.

If, then, these suggestions be true, it is incumbent upon us, as members of a conservative profession, which has to contend with just these disordered habits in the individual, in behalf of his mental and physical health, to carry this same attitude into our relations with social life. In the body politic, as well as in the body corporeal, we shall strive for purpose as against caprice, for control as against license, for order as against anarchy.

THE CARE OF THE INSANE IN LOCAL INSTITUTIONS.¹

BY ALBERT H. MOULTON, M.D., OF BOSTON.

The term insanity has included a great variety of abnormalities in different ages, and with the increasing light of scientific research will probably be made to embrace many forms of disease not so classified at present. As the terms morality, virtue, crime and luxury convey a dissimilar meaning to the people of different localities and countries, and to the same people at different periods, so the term insanity in its common acceptation depends upon the age and the people.

Without attempting to define the term, the condition referred to in this paper as Insanity is that in which the individual at the time is not considered responsible for his acts, and in which his liberty may be interfered with; or which to the popular mind comprises insanity.

Tradition, superstition, fanaticism and custom cling with almost unrelenting tenacity, influence our lives, and their effects disappear, if ever, after many fluctuations, by being overwhelmed with truth and reason.

¹ Read before the Massachusetts Medical Society, June 10, 1890, and recommended for publication by the Society.

When certain improper conditions in any branch will be replaced by rational methods depends upon the time when the subject is approached in a broad and scientific manner, born of intelligent experience.

The early settlers of this country copied many of the usages of the old country, not neglecting religious intolerance even, and the mistakes which were made on the British Isles and elsewhere across the water were repeated here, almost as a matter of necessity. The methods of dealing with the insane which our forefathers borrowed, and which they applied according to their light, as has every succeeding person, were crude, not to say cruel; for the reforms of Pinel and Connolly, who viewed the conditions with the eyes of professional experience as well as philanthropy, had not permeated the masses, and never during the time of those reformers was there asylum room for all the insane of their communities, most of whom were dealt with by laymen; therefore it was not the example of such physicians that our ancestors followed, but that which for long centuries had been set by incompetent and mistaken men, which, if ever studied a moment, was supposed to be rational and proper, and which is still influencing a large number of citizens in the treatment of many insane men and women. When this subject is studied, it is apparent that two methods of dealing with the insane have long been in vogue: by one they are treated as sick people, by the other as criminals or paupers; in one instance they are placed under the fostering care of the State, in the other their management is often sought by those inheriting the penurious and selfish methods of local politicians, or they fall into the care of well-meaning but incompetent persons. The results have been the same in all time, as I shall endeavor to show.

Tuke, in his "Insanity in Ancient and Modern Life," shows how it is probable that causes were in operation to occasion mental disease in pre-historic times; and if existing and recognized it must have had some sort of attention bestowed upon it, as was the case later. To that writer, also to Esquirol, Sibbald, Folsom and a few others, are we much indebted for valuable contributions upon the history of the early treatment of the insane; and to the gentlemen mentioned, as well as to Shew and Letchworth, do I make acknowledgment. Forms of insanity are portrayed in the Old Testament, and not infrequently spoken of in the New. David feigned insanity and betook himself to a cave. Jesus caused the unclean spirit to depart from a man who had been possessed, and who had spent days and nights in the mountains and tombs, crying and cutting himself with stones. He had often been bound with fetters and chains, which he always broke. It can reasonably be inferred that insanity was not considered really a *disease*, for Christ gave his disciples power against unclean spirits, and to heal all manner of disease. Probably the Greeks and Romans treated some of the insane in rooms adjoining their temples. Homer makes a single reference to the subject of insanity; and the dramatic writers of that time admirably described the disease. Euripides portrayed the insanity of Orestes, caused by having murdered his mother. He suffered from melancholia, followed by mania during which he had hallucinations of sight and hearing. When he fell exhausted, the herdsmen tried to stone him, and he was protected by a friend. The Athenians who lived as early as the fifth century before

Christ treated the insane with intelligence. A father suffering from insomnia and with increasing delusions of grandeur was the source of much anxiety to his son, who, after using moral suasion, which failed, had the patient bathed and purged. Fearing that he would escape, he was kept locked in his room under the care of a servant.

Among the stories told by Atheneus is one of a young man who had delusions of wealth; he was not a general paretic though, for under the care of a physician he recovered. Hippocrates regarded mental derangement somewhat in the nature of bodily disease, and Sibbald shows that the most cultivated intellects of Athens concurred with him.

The priests, among the ancient Egyptians, treated the insane by what we now term "moral" means; useful occupation and pleasant diversion, while the ceremonies attending the treatment of the insane at Gheel during its early days were as impressive upon the patients as those indulged in by Christian Scientists, Mind Curers and other quacks of the present day.

We are informed by Dr. Cowles, in his chapter upon Hospitals in "The Reference Hand Book of Medical Science," that "the first hospital for the insane on record was founded A. D. 491, at Jerusalem, and such asylums were established by the Saracens at a later period." During the dark and troublesome Middle Ages the insane suffered much; the intelligent and humane treatment which had been taught and practised "by the learned priests of Egypt, and later by the great philosophers and physicians of Greece," was lost sight of, and the insane came to be regarded as criminals and outcasts, and were treated accordingly, or if accused of being bewitched were burned at the stake. How many actually insane suffered such tortures will never be known. Says one historian, "it has been estimated that in Europe during the fifteenth and seventeenth centuries more than one hundred thousand persons were convicted of witchcraft and were burned, drowned or hanged. "In England," says Sibbald, "during the first eighty years of the seventeenth century, the number executed has been estimated at five hundred annually, making a frightful total of forty thousand. According to the proportions which are furnished by the statistics of insanity at the present day, a population such as that of England in the seventeenth century would have furnished about two thousand persons annually who would, according to our present views, have been placed in asylums"; and he makes the deduction that a proportion of nearly one out of every four persons who would now be sent to an asylum were burned as witches. During the epidemics which culminated in Essex County in 1692 (which never made any headway in the Plymouth Colony), but twenty-five persons were executed. None were burned in America because of this delusion.

Whipping-posts were common in England in the reign of Henry VIII, and Tuke refers to the fact that wandering lunatics were whipped. He has "no doubt" that "in addition to branks [gags] and whipping-posts, the pillory and stocks, and probably the ducking stool, were made use of for unruly and crazy people who nowadays would be comfortably located in an asylum."

Asylums were established in England, Spain and elsewhere, which were under the charge of monks, or were in reality prisons, subject to no supervision,

where the treatment was naturally barbarous and inhuman. It was generally imagined that the insane were possessed by demons, and dungeons were provided; unnecessary restraint was used, and the unfortunate inmates were subjected to all manner of abuse; they were looked upon as little superior to beasts, and were often treated worse than criminals at the beginning of the nineteenth century. Pinel, the alienist, after being long resisted by the Commune, finally got permission in 1792 to try his experiment, and he loosened the chains and bonds from numerous ill-fated inmates. William Tuke, in 1796, at the York Retreat, then just opened, renounced the use of chains and manacles in the treatment of the insane.

Connolly, in 1839, followed his example, introduced the system which spread over England and Scotland, at a time when Woodward was performing equally as good work in Massachusetts. Letchworth, in his recent work, "The Insane in Foreign Countries," after specifying certain barbarous methods of restraint in use at Bethlehem, remarks, "That cruelty of the kind described should have been possible as recent as the year 1815, twenty-five years after Pinel's great reform in France, and after Tuke's introduction of humane principles at the York Retreat, is almost beyond belief." Such a state is fully accounted for by the fact that, at the time spoken of, Bethlehem was nothing more than a prison-hospital, having no resident physician, where governmental supervision had been successfully resisted by the local management, and which was not effected until 1853, when the old régime was swept away and a new order of things introduced, which has made it one of the best hospitals in the world, directed by resident physicians and periodically inspected by public officials, (other than its board of managers,) as should be every place where the insane are kept. It will be shown that improvement and reform have been as slow of adoption in this country at a more recent date, as was the case in England at the time spoken of, and that the insane receive a full measure of justice only when treated by those who make their disease a study.

As the Biblical idea regarding insanity obtained for many centuries, so other false notions continued beside those of custody. Dr. Rush, in 1783, deemed it advisable "when visiting an insane person to first look him out of countenance," a procedure which some, unacquainted with insanity, still imagine necessary to attempt.

It was generally supposed there was an exacerbation of excitement at the full of the moon, an idea of great antiquity, and one which has such a hold that it effects even the titles of hospitals and makes standard a legal appellation.

That insanity can be diagnosticated by some appearance of the eyes of the patient (what I know not) is still a common belief.

Thus I have referred to a few of the circumstances, customs and traditions which greatly influenced our ancestors in dealing with this subject, and they should be kept in mind when attempting to give a reason for the methods and theories long ago adopted, very many of which are still entertained by individuals who have not had an opportunity of correcting them, or upon whom superstition, credulity and love for the marvellous have a strong hold.

It is the theory of the layman which the layman adopts, especially so in a land with few papers and poor

communication; hence in the early history of this country the insane were naturally treated as criminals and outcasts. Only the demonstrative forms of the affection were recognized (not generally as disease), and those suffering from it were consigned to almshouses and locked up in jails, where they were long forgotten, while the quiet and demented wandered about the country. Understanding these natural circumstances and their causes, one is not surprised at the conditions, for the people knew no better method, but can feel nothing save admiration for those who recognized the mistakes that had been made, and through whose efforts reformation was begun.

In Massachusetts, to Horace Mann more credit is due than to any other person for arousing public sentiment which demanded humane treatment of the insane. Largely through his efforts the first State hospital was established (opened in 1833) of which he became a trustee. It was intended to have the Commonwealth assume the whole care of the indigent insane, and to the hospital were sent insane from almshouses and prisons in such numbers that within a year the institution was overflowing, and to make room for more curable cases, patients who had enjoyed the benefits of the hospital unrestricted were returned to their old filthy quarters where manacles and chains were resumed, a most emphatic illustration of the two methods under comparison.

In 1843, ten years after the opening of the Massachusetts State Hospital, Miss Dix memorialized the legislature in a document of thirty-two printed pages, that the institution be enlarged. The fact that the barbarities to which the insane had long been subjected had been condemned by governors, commissioners and others, and that a hospital had for a decade been under the care of the most distinguished specialist in America, was not sufficient to prevent methods discreditable to any community. Miss Dix found patients in "cages, closets, cellars, stables and pens;" many were chained, naked, beaten with rods and lashed into obedience. She named forty towns, often with much detail, where such cruelties existed.

To one who has recently gone over the ground covered by that noble woman forty-seven years ago, her record is most suggestive, not an inconsiderable part of which can be duplicated. She spoke often of cages and shackles, but had more to say about the improper mingling of the sexes, untidiness, etc. There has been great improvement in our hospitals since the time spoken of, every one of which could properly adopt the motto, "Not how cheaply, but how well can I do my work," and the insane in almshouses are better cared for, yet the difference between the two forms of care is, I believe, as great now as it was fifty years ago. The state of the latter institutions is no new condition, and it will continue in some degree as long as the present methods obtain.

The memorial spoken of caused an investigation to be made by a legislative committee, which recorded its testimony against practices of which every unprejudiced individual is a foe.

At about the same time a committee, of which Dr. S. G. Howe was chairman, studied the condition and methods of the care of the insane, and in its report specified with minuteness cases of neglect, showed how the insane degenerate when placed in almshouses, and, after reviewing the whole field, recommended that the State take charge of them.

Again, in 1863, when one would suppose sufficient time had elapsed to remedy all these evils, another commission carefully studied the subject of insanity and the disposition of the insane. So comprehensive is that report that I should like to embody it in this paper; I will, however, make only a limited quotation: "Your commissioners entered on their duties with the impression that the noble institution established by the State had removed all the principal causes of complaint. They knew that in former times men had been shut up in cages and treated almost like wild beasts, but they were unprepared to find instances of such unnecessary cruelty in the State of Massachusetts at the present time. . . . The overseers of the poor can confine any pauper as a lunatic without the intervention of a judge and without the certificate of a physician, and when confined it is the duty of no one who is not interested in reducing the expenses of the town to visit the lunatic and see that he is properly cared for. The manner in which maniacs are confined in some of our towns requires immediate legislative interference."

Under the direction of the State Board of Lunacy and Charity, the writer has recently visited, or caused to be visited all of the almshouses in this state where there are insane. In many the sexes are not properly separated, they are often untidy, and the patients are subjected to a great amount of unnecessary restraint. Some female patients are under the care of men, and in only a few instances do the insane receive care which approaches that bestowed upon a similar class at the State hospitals, the question usually being one of custody alone.

But in justice to Massachusetts I turn to other states, for evidence is universal that under the supervision of the Commonwealth the insane receive better care and in the end are more economically provided for (because more recoveries result) than is the case when placed under non-professional supervision.

After procuring the enlargement of the Worcester Hospital, Miss Dix got the Providence Hospital reconstructed, and then began the work of founding outright state asylums, starting with New Jersey and Pennsylvania, and year by year carrying bills through the legislatures of twenty states. Did time permit it would be interesting, because the lesson is a vital one, to follow her steps and study the testimony of those who went after her; but only a few instances will be taken up in some of the representative states. They all point to the same conclusions.

New Hampshire has ten county asylums and almshouses, at which most of the town and county pauper insane are cared for. They are simply places of detention, and the treatment of the insane has been of a low order. They have recently come under the care of the new Lunacy Commission, which has removed a considerable number of patients to the State Asylum.

The Board of Public Charities of Pennsylvania said to its Legislature in 1873, regarding the insane in prisons and almshouses: "The shocking and sickening revelations so graphically set forth by Miss Dix in 1845 were not yet obsolete," and suggestively remarked "some improvement had been made in some of the places." Again, in 1885, the Committee on Lunacy of the Pennsylvania Board of Public Charities reported various cases of abuse and other improper treatment of insane found in various localities, and

they characterized the county poor-houses as "seldom what they should be," "where proper requirements seemed onerous and exacting to the authorities, who are often the faithful representatives of a parsimonious public."

I am informed by an official of the State of Connecticut that throughout that Commonwealth there are many wretched almshouses where demented, harmless people are kept, some of whom "are greatly neglected and without medical care for their special ailment, and under no sort of systematic observation by a physician."

Michigan struggled long with this question, and "a year ago county care became a thing of the past. It continued during its entire existence to be a reproach to the county."

The new Lunacy Commissioners of New York have investigated the local asylums in that State. In their report, after reviewing the history of their asylums from the time that Governor Throop, in 1830, called attention to "the privation and neglect to which the insane were subjected in the county poor-houses," the interesting story is related of how the insane are likely to be circumstanced in such institutions. Without going into particulars as to the non-separation of the sexes, lack of proper medical care, the abuse, exposure and filth, it is enough to say that the recommendations have been adopted, and the insane now in county asylums are to be provided for in State hospitals.

A report comes through the daily papers from an almshouse in Maine, where an insane man escaped from his cage and carried out an often-repeated threat by setting fire to the detached building in which he and a bed-ridden woman lived, watching with pleasure the flames as they consumed his companion.

Fortunately we seldom see such an example of what non-medical management of the insane as a business may be, and to what it is likely to lead, as that exhibited at Longe Pointe, near Quebec. An asylum barely large enough for one thousand, is said to have been packed with seventeen hundred and thirty inmates, the basement and attic in constant use for patients, the latter place in July and August as hot as the infernal region. I am informed that the government of Quebec paid to the owners (of course not physicians) one hundred dollars a year for the care of each pauper patient. Since the contract with the government in 1873, they have made, so the papers report, nearly three quarters of a million at one hundred dollars per patient!! Can we wonder that there was want of fire protection, that there was wholesale restraint (to save bedding and clothing), confinement of patients in bare kennels in which were neither light nor air? Dr. D. Hack Tuke, the well-known alienist and author of London, inspected that place in 1884, and made a report of severe but just criticism. He characterized some portions of the buildings as chambers of horror, and said he should regard the Angel of Death as the most merciful visitant those wretched beings could possibly welcome. It is to be hoped, that if the asylum is rebuilt, the contract system will be abandoned, the direction of affairs entrusted to a competent medical superintendent, and the whole placed under the supervision of a board of charity.

With our hospitals and asylums all overflowing, hundreds of insane in almshouses, many of whom are poorly cared for, and cases accumulating at the rate of

about two hundred a year, the question for solution is one which interests general practitioners and specialists alike. Many of our almshouses, besides being put to their legitimate use (which is an honorable one) have, to use the language of another, "become receptacles to which may be assigned everything in the line of vice, crime and misfortune that has no other resting place": they are patronized by people too lazy to work; the designing attempt, and often succeed, to make them refuges; some are workhouses, in name, most of the smaller ones lodge tramps, while at some truant schools are maintained.

With such a mixed population it is not to be expected (it is surely not the case) that the mentally sick can receive proper attention, where the amount of help is the lowest that can be endured, where the persons employed are usually inexperienced, seldom knowing anything about the care of the sick and not infrequently being unsettled and incompetent.

We do not hear it claimed that almshouse wardens can treat pneumonia, asthma or albuminuria, and I am unwilling to relinquish the belief that insanity of long standing is no less a disease, from which a goodly number will recover if unremittingly treated, and that its treatment should not be left to the ignorance of persons who may be well-fitted for other vocations.

Most of the insane who are a public charge are so not because they are primarily paupers, but they become impoverished in consequence of the disease, and in losing the power to support themselves, their families often become more or less dependent; hence it is not too much to maintain that this unfortunate class has a claim upon the Commonwealth out of all proportion to that of the ordinary pauper, who is often such by choice or vice.

With this fragmentary retrospect, in which not a tithe of the evidence at hand has been used, I trust I am warranted in presenting the following propositions:

(1) There has been great improvement in the care of the insane in this country, both in almshouses and hospitals since the establishment of the latter.

(2) The same degree of difference between almshouse and hospital care has continued.

(3) The best method to follow is that in which the State assumes the whole care and expense of the entire number of indigent insane.

A CASE OF VAGINAL HYSTERECTOMY.

BY F. H. DAVENPORT, M.D.
Instructor in Gynecology, Harvard Medical School.

Mrs. L. was first seen by me, in consultation with Dr. Hodgdon of Dedham, on October 22, 1888. She was forty-three years of age, had been married twenty-one years, and was the mother of ten children. She had also had three miscarriages, the last four years before, from which event she dated her present trouble.

Her symptoms had been a constant vaginal discharge, profuse enough the last four years to require the use of a napkin, since April becoming offensive and bloody. Her menstruation began at seventeen, and was always irregular, occurring since her marriage every three weeks, lasting a week, and using from twenty to twenty-five napkins. For the last four years,

flowing has been irregular, since July constant, so that she cannot tell when the regular menstruation should occur. During this time she has used from two to three napkins a day. She complains of constant pain in the sacrum, worse when on her feet, also bearing-down pain. She has had symptoms of cystitis for two years. She says that three years ago an "abscess in the uterus" was incised, and that two years ago a polypus was removed by a physician in New Bedford. Her general health has suffered greatly from the constant drain, and she has been obliged to give up her work, which is that of a nurse.

She was advised to enter the Free Hospital for Women, which she did a week later. Examination showed a large, soft uterus, cavity three and a half inches, bleeding freely on introduction of probe, cervix bi-laterally lacerated. Under ether the canal was stretched and the interior of the uterus curetted. One or two teaspoonsfuls of soft, shreddy tissue was removed, which was sent to Dr. W. F. Whitney for examination. His report was that there was no evidence of malignancy in the specimen sent. The patient was therefore advised to return home and await results.

She re-entered April 27, 1889, with a history of increased pain and flowing. She used from three to twenty napkins every day, and was so weak that she had to keep her bed most of the time. The foul-smelling discharge had returned.

May 4th, I performed hysterectomy, assisted by Dr. H. C. Baldwin. The anterior cul-de-sac was first opened with scissors, the bladder was then dissected off from the uterus with the fingers, and the peritoneal cavity opened from one broad ligament to the other. The same was done in the posterior cul-de-sac. The left broad ligament was then grasped with the thumb and fore-finger, and a pair of strong clamp forceps applied, including about half the breadth of the ligament. The tissues between the clamp and the uterus were then divided with scissors. A second clamp was then so placed as to include the upper part of the ligament, and the tissues here were also divided with the scissors. The same was done on the other side, and the uterus was easily drawn down and out. The right ovary and tube appearing with the uterus, they were clamped and removed; the left not appearing, was allowed to remain. There was comparatively little hemorrhage. The handles of the forceps were securely tied to prevent slipping, and a moderate amount of iodoform gauze was packed into the vagina and around the handles.

The patient made a good recovery from the operation, the temperature reaching 102° once only, on the second day. The clamps were removed at the end of forty-eight hours. On the thirteenth day after operation there was severe pain, and two dark gray, foul-smelling masses were passed from the vagina. These were presumably the sloughs from the tissue compressed by the forceps.

She left the hospital in good condition June 28th, the vaginal wound being entirely healed. Dr. Whitney gave the following report of the condition of the uterus:

"The whole cavity measures eight centimetres (the body five, and the cervix three). The walls, at the fundus, are three centimetres thick. There seems to be a general increase of fibrous tissue in the walls, especially in the cervical region. The external os presents numerous slight superficial erosions."

¹ Read before the Obstetrical Society of Boston, May 10, 1890.

"The mucous membrane is about twice as thick as normal, slightly folded, and of a reddish-gray color."

"Microscopic examination shows a great increase of the tubular glands in relation to the basic substance. There seems no evidence, however, of any tendency on their part to grow into the muscular substance."

"I should regard the case, therefore, as one of extreme hyperplastic endometritis."

"The ovary seemed normal, and at one end was a reddish-gray, slightly opaque mass, with a deep-red centre and crinkled edges, measuring two centimetres in diameter—a false corpus luteum."

The patient was seen May 9, 1890, a year after the operation, and as regards the pelvic organs the condition was very satisfactory. There was no evidence of any trouble at the seat of the operation. She had had a very severe attack of the "grippe," which had laid her up for weeks, and she had various symptoms which suggested trouble with the kidneys. Dr. Wood examined the urine, and reported a condition of hyperemia of those organs.

The justification for the operation lies in the long duration of the disease—four years—in spite of two, and possibly three operations for her relief; the increasing severity of the hemorrhage and discharge compelling her to give up her work on which she was dependent; the possibility of malignant disease, owing to the difficulty of making a diagnosis from the fragments removed; and also the fact that there was a clear history of cancer in two or three members of her immediate family.

A CASE OF CALCAREOUS FIBRO-MYOMA OF THE UTERUS.¹

BY WILLIAM INGALLS, M.D.

PATIENT sixty-three years of age: married; was never pregnant; menopause at or about forty.

March 16, 1890. First visit. Previous history that of one whose household duties and cares had over-powered will and physical strength. The prevailing symptom of her present condition was a comparatively moderate but uncomfortable distention by gas in the intestines, which increased, not very rapidly, but yet towards the end became very distressful. Treatment was unavailing. There were hours of quiet sleep within each twenty-four; but, for the most part, discomfort and pain overcame her phenomenal patience and pluck.

On examining the abdomen twelve hours after death, it was found to be greatly distended. A large quantity of gas escaped when the peritoneum was punctured. Exposure of the intestines presented great distention; color dark; appearance of recent limited peritonitis over descending colon. Several points at various portions of the intestines gave evidence of impending perforations, and at slightest touch, openings took place; and through these issued an immense quantity of nearly black, grumous and foul-smelling fecal matter. Following the intestines down to the rectum, a large substance, hard and rough, was felt, which proved to be lying behind the bladder, between that and the uterus, which was small, hard and nodulated. The hard substance had pinched in bit of small intestine, a portion of which, above and below, was cut off and removed with the mass. Throughout the case, urination was performed normally.

¹ Read before the Obstetrical Society of Boston, May 10, 1890.

Dr. C. E. Stedman saw the case with me. Dr. W. W. Gannett kindly examined the specimen, and the following is his report:

"A hard, firm mass, having two lobes—the larger the size of a big hen's egg, the smaller the size of a walnut. The two lobes are intimately adherent to each other. The outer surface is rough and irregular, is covered with fibrous tissue; and at one point a bit of small intestine is attached by a mass of fibrous tissue.

"The mass, when sawn through, is found to have an outer shell of calcareous matter, and an inner portion made up in part of cheesy material, but in great part of a very tough fibrous material. Microscopically, this is found to be fibrous tissue, with a fatty detritus.

"The mass is a sub-peritoneal fibro-myoma, which has become detached from the uterus, and has undergone a partial fatty degeneration, and calcification of the outer part, forming a shell."

A CASE OF VAGINAL HYSTERECTOMY FOR CANCER: RECOVERY.¹

BY JOHN HOMANS, M.D.

Mrs. T., fifty years old, entered the Massachusetts General Hospital with the following history:

Had borne three children: the youngest is now twenty-six years old. The menopause had taken place at the age of forty-five. For the last three years she had had a reddish-yellow discharge from the vagina, small in amount, at times rather offensive. During the last few months has lost considerably in weight. A sister died of cancer.

On examination, the uterus was found somewhat enlarged, the cervix thickened and eroded. A piece was cut off and sent to Dr. Whitney, who reported that it was cancer. The broad ligaments did not seem to be involved.

An operation was performed May 2, 1890. The mucous membrane was cut through with a knife, entirely around the os uteri. The bladder was pushed off from the uterus with the finger, traction being made on the uterus by an assistant with very strong vulsellæ. The vagina was continually irrigated with a very weak solution of corrosive sublimate. The uterine wall was found to be nearly perforated by the disease at the junction of the neck and body. Posteriorly the uterus was separated from the rectum by the finger, and the peritoneum opened behind. The fingers were then pushed over the fundus from behind, and the anterior cul-de-sac opened. Two long pairs of interlocking forceps were clamped on each broad ligament, and the uterus was cut away on each side with scissors. At this stage of the operation the uterus tore in halves, and the upper and larger part, containing the body and fundus, receded into the abdominal cavity and the intestines appeared in the vagina. By bimanual pressure the uterus was made to reappear in the vagina, and one of the round ligaments was caught in a pair of compressing forceps, and by this hold the uterus was extracted. The forceps were left hanging from the vagina, one pair on each broad ligament, and one pair on each Fallopian tube. The pulse was 70 at the beginning of the operation, and the same at its close. The operation lasted about half an hour.

¹ Read before the Obstetrical Society of Boston, May 10, 1890.

The temperature reached 101° on the fourth day, and has since declined. The forceps were removed on the sixth day. Recovery rapid. No pain.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING, May 10, 1890.

DR. DAVENPORT reported

A CASE OF VAGINAL HYSTERECTOMY.¹

DR. A. H. HODGDON of Dedham, a guest, said that a radical operation seemed more to be demanded in this case from the fact that the father had had cancer of the face and a sister was suffering with undoubted cancer of the uterus. The operation was certainly a successful one and the patient would be in good health to-day were it not for the renal disease.

DR. HOMANS wished to make a practical point, that as regards the clamps it was best to let well enough alone and not remove them too soon. In the case he was about to report he left the clamps on till the sixth day. In another case a clamp was removed on the fourth day and had to be put on again after the loss of about a pint of blood.

DR. Homans then reported

A CASE OF VAGINAL HYSTERECTOMY FOR CANCER. RECOVERY.²

The specimen was shown.

DR. Homans said that he thought this operation for cancer of the uterus was a very proper one if the broad ligaments were not affected, and the removal of a foul sloughing mass cannot but be beneficial. Inference as to the duration of life in these cases can be drawn with little certainty, and he recalled a case which he thought would die in a short time that lived a year. Another case where the diagnosis of cancer had been made by the microscope, which he had scraped and burnt three years ago, is still living.

Another similar case died in six months, so it is therefore somewhat problematical whether we really add to the duration of life or not by an operation.

If the diagnosis of cancer is made he considered vaginal hysterectomy the best operation and the modern method is so much surer and quicker than the old method.

Owing to the remote position of the disease we rarely see these cases until the disease has progressed too far. A case where the disease had extended, in which he refused to operate, went to New York, where the uterus was removed and also some of the bladder, leaving a large fistula.

A case he had cured at the Carney Hospital ten or fifteen years ago for hyperplastic endometritis, developed two years later an enormous soft abdominal tumor, which he took to be a sarcoma and could not remove.

DR. BAKER spoke of the relative advantages of hysterectomy and of his method of high amputation of the cervix, and he showed that, although hysterectomy was the proper operation in some cases yet the majority

of the cases of cancer of the uterus were best treated by the high operation.

He then illustrated by two cases (showing the specimens), the first belonging to a class where hysterectomy only is advisable and proper, the second, one that was best treated by high amputation.

CASE I was referred to me by Dr. Sinclair of this city. Diagnosis from specimen removed by Dr. Sinclair and submitted to Dr. Whitney for examination, "malignant adenoma."

I first saw her February 14, 1890.

History as follows:

E. J., age fifty-six; married twenty-two years; no children. One abortion at three months soon after marriage. Menstruation always regular. Menopause two or three years ago. Twelve or fourteen years ago had pain in left groin for a month or so. Pain and soreness across lower abdomen for last two years, pain of a dull character and worse at evening and in the night; very severe at times. When pain began two years ago there was a considerable flowing with clots; since then a slight show every day. Last November a copious hemorrhage (a vessel full) lasting three days. Lately the pain is worse, increased by constipation. General health good.

February 17th with the assistance of Dr. Sinclair I operated. I did the usual operation, using two stout ligatures on the left broad ligament, then clamping with a Cleveland bent clamp and dividing tissues inside it with the cautery — the same process was repeated on the right side. I stitched the vaginal mucous membrane at the edges of the incision, both in front and behind the uterus, to the peritoneum and in this way lessened the hemorrhage.

It was found to be difficult to deliver the fundus because of its large size and the presence of numerous fibroid nodules. Fundus antevected and delivered. Brisk hemorrhage from the right broad ligament, during the operation, due to slipping of one of the clamps; clamp on that side reinforced with an extra (short) clamp. Ovaries and tubes left behind. Clamps lashed and vagina packed with iodoform gauze. (Length of operation two and one-half hours.)

Patient rallied well from operation, passed fifteen ounces of urine in first twenty-four hours. Clamps removed in forty-two hours. No hemorrhage; no temperature. Douches of corrosive 1-5000.

Dr. Whitney, who examined the specimen, reported as follows:

The cervix had been destroyed by the disease. The portion of the uterus remaining measured about eight centimetres in length. The walls were thickened and the mucous membrane replaced by a soft grayish, slightly opaque, shaggy and slightly polypoid growth which measured about one centimetre in thickness and could be followed some distance further between the bundles of muscular fibres.

Microscopic examination showed this new growth to be made of large tubercular glands very closely packed together and irregular in size, shape and distribution, in the most abundant parts assuming more the appearance of ordinary cancer, while in the younger growth their tubercular character was more easily made out. From these characteristics the diagnosis is of malignant adenoma starting from the mucous membrane of the uterus. "As far as can be determined the new growth seems to be confined to the parts removed."

The ligatures were removed on February 26th, they

¹ See page 200 of the Journal.

² See page 201 of the Journal.

being then found free in the wound. Patient had an attack of persistent vomiting on the 22d, aside from this she had no bad symptoms.

At time of her discharge from the hospital March 17th, the wound in the vagina had healed. There was a slight abrasion in left vagina vault.

April 25th. Specimen removed and sent to Dr. Whitney who reports: "Granulation Tissue."

CASE II. Miss M. R., forty-seven years of age. Seen October 31, 1888. Menstruation began at fourteen; always regular till last year; flowed five days, eight or nine napkins; no pain to speak of. The past year has been irregular, but for the most part has flowed oftener and longer, or has had a little bloody discharge. Some leucorrhœa of a watery character lately; foul odor and acrid. Bowels incline to constipation. Micturition frequent for years. Has had some sharp, shooting pains in region of rectum, and lately has been waked at night with acute pain in lower abdomen. Walking or standing tires her very much. Has gained flesh in the past year; sleep restless; nervous; appetite good; digestion fair. Last catamenia just over.

Operation November 1st. High amputation, my customary operation.

DR. STRONG said that, theoretically, the removal of the whole of a diseased organ should insure greater safety and immunity from a return of the malignant condition than removal of a part, which was all that was accomplished in high amputation. The fact that statistics show a higher percentage of return after total extirpation than after high amputation, was undoubtedly because the cases were not selected with the same care. The operation being comparatively new, and still, as it were, on trial, many patients underwent the operation, although the disease had invaded on either side the broad ligament. No operation, of course, could stay the progress when once it had reached this point. On the other hand, the limits of the operation of high amputation had been so thoroughly established, that cases were divided distinctly into two classes: first, where it was performed as a radical operation, with the idea of removing entirely the disease; and, secondly, where it was performed only as a palliative measure, and in compiling statistics these two classes were kept very distinct. That high amputation should compare so favorably with total extirpation in cases of epithelioma of the cervix, is due to the fact that the disease progresses outwardly upon the vagina and into the broad ligaments more rapidly than up the cervical canal and into the body of the uterus: therefore, if a case is seen in a sufficiently early stage, before these parts are invaded, it is rarely found impossible to amputate high enough to remove the whole growth.

With regard to the distinction between hyperplasia of the lining membrane of the uterus and malignant adenoma, a microscopical examination of the scrapings is a very unsatisfactory and often erroneous method of arriving at a diagnosis. Clinical considerations of the case outweigh that evidence. The one point the speaker has seen clinically demonstrated several times, but not often alluded to as a diagnostic fact, is, that the amount of tissue which can be removed in malignant adenoma by the sharp curette, is much less, usually, than that which is removed by curetting of hyperplastic endometritis, although the preceding hemorrhage may have been quite as severe. Repeated return of hemorrhage and discharge after curettings do not necessarily mean malignant disease. One case, in which he had

operated three times at intervals of six months, and which had previously been operated upon twice at intervals of a year, was completely cured and has remained so for six years, there having not been a single hemorrhage, and the patient being perfectly well. In another case, which he has under observation at the present time, the hyperplasia assumes the form of quite large polypi, which are removed by forceps more easily than by curette, and which grow with such rapidity that dilatation and cleaning out of the uterus is required at intervals of three months, and nothing of a malignant nature has ever been demonstrated, nor does the patient's health seem at all impaired. The uterus is steadily decreasing in size and a cure may ultimately be expected. In both of these cases large masses were removed. In another case, in which the disease was assumed to be malignant at first, the patient was cured twice after an interval of eighteen months; a very small quantity of tissue was removed each time, but the disease extended steadily and passed out along the course of the Fallopian tubes, subsequently involving the peritoneum, and causing death. This patient refused extirpation.

The development of renal disease in the case reported by Dr. Davenport is very interesting to the speaker, because he has found very frequently the advanced cases of both epithelioma of the cervix and cancer of the body of the uterus, terminating with this as a fatal complication. In choosing between the two operations of total extirpation and high amputation, it seems to the speaker that a great deal more weight should be given to the difference in severity of the two operations. Unless one thoroughly examines, under ether, and feels perfectly sure that the parts surrounding the uterus are not participating in the disease, total extirpation should not be performed, as the immediate shock, the complications following and during healing of the wound, are certainly far greater. In epithelioma of the cervix, which has involved the vagina, a free dissection and extirpation of the diseased vaginal portion, accompanied by high amputation of the cervix, is just as effectual as total extirpation of the organ, in his experience. One case in particular, which he has seen within a few days, in which he removed nearly the whole of the posterior wall of the vagina and a portion of the anterior wall and the cervix, and stitched the raw edges of the vagina to the stump, occluding the peritoneal cavity, made a perfect uninterrupted convalescence, and, twenty-eight months after the operation, there has been no sign whatever of return.

With regard to the use of the actual cautery at the time of the operation, and subsequent applications of caustics to insure further sloughing, his experience has been very satisfactory. The caustic which he employs is a solution of chloride of zinc, dissolved in equal parts of water, drachm for drachm: packed carefully and thoroughly into the wound left by the operation, as soon as the slough from the actual cautery has come away. This application is very painful for a matter of twelve hours or so, but after that it causes no trouble. The slough from this extends very deeply, but not so rapidly as to perforate the peritoneum. For those advanced cases of cancer in which the infiltration precludes any possibility of radical measures, and in which an operation of any magnitude would probably open the rectum or the bladder, the speaker thinks that just as little in the way of

operative treatment should be employed as possible. If the curettes and caustics be employed with a free hand, and a fistula is established into either of these organs, the patient's state certainly is not benefited, but a new misery is added to those with which she already contends. In these cases, his practice is to simply remove by gentle curetting the superficial mass of granulations, and repeating this as often as may be necessary to check any troublesome haemorrhage, and to trust that the disease in its natural course may extend so slowly as not to establish fistulae.

DR. BLAKE said that he was rarely so fortunate as to see cases early enough to operate on. The cases at the City Hospital were generally in advanced stages. He relied on curetting and the use of chronic acid.

DR. STRONG agreed with the last speaker that the majority of cases of cancer of the uterus did not present themselves until it was too late.

DR. BAKER said that the lateral extension of cancer of the uterus was a serious obstacle to operation, but the extension of the growth posteriorly into the upper wall of the vagina was not so important as that part can be removed, and he instanced a recent case where about half of the uterus was removed with a portion of the vagina behind; the vagina was then stitched to the uterus. Extension of the growth anteriorly is more serious, as we must then remove part of the bladder, leaving a fistula which has to be closed subsequently.

DR. INGALLS reported

A CASE OF CALCAREOUS FIBRO-MYOMA OF THE UTERUS,³

and showed the interesting specimen.

DR. HOMANS had seen cases where after the detachment of the fibro-myoma from the uterus, adhesions formed in such a way that loops of the intestine became strangulated and death was the result.

DR. DAVENPORT showed a

VESICAL CALCULUS REMOVED BY VAGINAL LITHOTOMY.

The patient, who was sixty-six years of age, had had vesical symptoms for ten years, being slight at first, but for six years severe enough to prevent her riding in a carriage, and forcing her to walk as little as possible. At first there had been an occasional sudden stoppage of the urine, lately not. Perhaps twenty times in all she had noticed blood in the urine after unusual exertion. The principal symptom was pain and dragging in the region of the bladder when she was on her feet for any length of time.

The stone was easily detected on vaginal examination. At the operation it was found that an incision two inches long reaching from the neck of the bladder to the cervix was not large enough to allow the stone to pass, so a second incision half an inch in length was made at right angles to it, beginning near the middle of the first incision. Through this the stone was with considerable difficulty extrated. The wound was immediately closed with eleven silver wire sutures. The convalescence was uninterrupted, the temperature never going above 99.5°, and the fistula healed throughout by first intention. She has several times since held the urine between five and six hours. The stone was examined by Dr. Wood and found to be pure uric acid. It weighed 1,200 grains.

THE NEW YORK ACADEMY OF MEDICINE. SECTION ON THEORY AND PRACTICE OF MEDICINE.

STATED MEETING, May 20, 1890, FRANCIS DELAFIELD, M.D., Chairman.

DR. W. B. WOOD read a paper on the

AFTER-TREATMENT OF OBSTETRIC CASES.

Without claiming originality for the views he wished to present, he said that the method of treatment which he advocated differed sufficiently from that commonly adopted to make the subject, he hoped, one of considerable interest. For some time past it had been a matter of observation to him that the number of cases of laceration of the cervix was really much greater than would appear from any statistics that had ever been published on the subject. In fact, he now believed that at best slight cervical laceration takes place in every one who gives birth to a child. Very many cases escaped notice because nature acted so promptly that the slighter degrees of laceration were repaired before the accoucheur made his examination.

During the past five years he had worked on the theory that if the slight forms of laceration were so ready to heal without any attention on the part of the physician, the severer ones would spontaneously heal in the same kind manner if the proper conditions for the accomplishment of this purpose were afforded. In his hands not only in no case had a fresh laceration remained unhealed, but in many older cases successful repair had taken place without any operative interference whatever. The importance of the method in question in preventing trouble could be readily appreciated. The best skill could not prevent, but could only modify and control laceration of the cervix. It had often been alleged that there was no more reason why parturition should be attended by such accidents than was the case among savage tribes; but such a statement was absurd. The fact that was pertinent to the question at issue, and that was quite sufficient to explain the results commonly met with, was, that as civilization advances the cranium increases in size, while the pelvic diameters diminish.

Outside of laceration of the cervix, there was no other condition following parturition which occasioned so much trouble as arrested involution. Five years' experience in the matter, however, had convinced him that this would yield to the same treatment. According to the best authorities it required from six to ten weeks for the uterus to return to its normal size and weight, and from three to four weeks for the vagina, and from six to twelve weeks for the relaxed uterine ligaments and appendages to resume their normal condition after confinement. Yet ordinarily it was in the second week, while involution was still far from completion and any lacerations that might have occurred during labor were still unhealed, that the woman was allowed to get up and go about. In consequence, the uterus dropped downwards and tipped out of its normal position; and under these circumstances it was not to be wondered at that the health of the patient became permanently impaired. The evils resulting had been admirably summed up by Emmet in his work on "Diseases of Women."

From his observations he was firmly convinced that these evil results could be avoided by the observance of proper precautions both before and after the puerperal period. Before her confinement the patient

should be educated up to a correct appreciation of the dangers attending them and of the appropriate means for escaping them. It was a fact that up to the present time the human uterus had never become thoroughly adjusted to the upright position, and that it could be said to be perfectly held in place only when the woman was in the genu-pectoral posture, or that of the quadruped. Under the most favorable circumstances it could be readily seen, therefore, how easy it was for the organ to slip out of position.

The treatment which he practised and advocated after ordinary labor was as follows: He kept the patient in bed for four weeks, and during fourteen to twenty-one days of this time she was to be kept strictly on her back. At the end of twenty-one days he made an examination, with the patient in Sims's position. After this hot vaginal injections were employed, after the manner of Emmet, if no lacerations were found to remain. If there were any lacerations the injections were to be omitted, as tending to interfere with the healing process. At the end of four weeks, if there were no abnormal conditions present, the patient was permitted to get out of bed; but before she did so she was placed in the genu-pectoral position, and the uterus was carefully supported before and behind by borated-glycerine cotton pads. Finally, the physician was to make an examination of the patient once a month for a year following her confinement, in order to see that no displacement of the uterus or abnormal condition had resulted.

In hospital and charity work such a course was impracticable; but in private practice it should be insisted on, and it would readily be consented to by the patient if she were properly educated up to it. There were few women to be found who would not willingly submit to any course of treatment which would relieve them from the necessity of an operation; and if in the case of any patient suffering from a laceration of the cervix resulting from a former labor, it was represented to her that with the observance of proper care after next confinement the trouble could be obviated without a resort to operative measures, the chances were that she would most cheerfully consent to the treatment prescribed.

Dr. Wood then referred to the matter of lactation, and said that, while nursing undoubtedly furnished a favorable stimulus to the uterus while undergoing involution, in many cases the advantages arising from this were more than counterbalanced by the evil effects of the drain upon the general system caused by it; and hence, in order that the woman might be afforded the most satisfactory conditions for a complete restoration to health after her confinement, it was often necessary that the infant should be weaned at an early period. In conclusion, he said that within the past few years the advances made in obstetrics and gynecology had resulted in an appreciable decrease in mortality from childbirth, as regards both the mother and the infant; and it only remained that we should adopt an after-treatment in cases of midwifery which would prevent subinvolution and permanent lacerations.

DR. J. WEST ROOSEVELT read a paper on

THE GROSS ANATOMY OF CHRONIC PULMONARY CONSUMPTION IN RELATION TO DIAGNOSIS AND PROGNOSIS.

He said that while the evidence of the existence of tuberculosis afforded by the discovery of the Koch

bacilli in the sputa was naturally absolutely unassailable, the absence of the bacteria must always leave a doubt in the mind as to the presence of the disease. There were so many important precautions to be observed, however, before the absence of bacilli could really be held to exclude consumption, that it was necessary to be very careful in estimating the value of negative observations. To exclude the disease by negative results in searching for bacilli it was necessary, first, that the examination be made by an expert examiner with a good microscope and good dyes; second, that a sufficient quantity of sputum be obtained and, third, that a very large number of observations extending over a considerable time be made. In all cases of suspected tuberculosis, however, the element of time was a very important one, and it would not do to waste too much time in examining the sputa. It was always to be remembered that it was not the bacilli in the sputa, but those left in the lungs that were to be feared; and hence we should not give the latter a good chance to increase while looking for the former.

It was natural that the results of the labors of both Laennec and Koch should have been misjudged, especially in respect to their value as negative evidence. In each case their value as positive evidence had been enormous; the bacillus, so far as we know, affording absolute proof. Positive evidence was naturally that first sought. In the case of almost all important additions to scientific knowledge the first general idea after accepting the facts was to see what they positively proved to exist. Long after this came the question of what they do not demonstrate; and of both Laennec and Koch's discoveries it might be said that this value of positive evidence was so great that their importance in excluding disease had been over-estimated.

In the present study we had nothing to do, he said, with the finer details of pathological anatomy. In order to understand his point of view, however, it was necessary to admit the following things: (1) The discovery of tubercle bacilli in the sputa furnishes positive evidence of consumption, or of tuberculosis somewhere in the air passages. (2) Chronic consumption of the lungs occurs sometimes in a form in which the lesions consist of more or less distantly separated small nodules, and sometimes in a form in which there is more or less widespread solidification of the lung. In either of these forms cavities may be found. In both the lesion first invades, in a large majority of cases, the apices of the lungs.

This anatomical classification was of importance mainly for diagnostic and prognostic purposes, and did not pretend to histological accuracy. The first variety, the discrete, embraced those cases which Delafield had placed in the first division of the class designated by him as chronic miliary tuberculosis. It also embraced certain cases belonging to Delafield's second subdivision, in which, beside tubercles, there is new fibrous tissue. In short, it was intended to mean any form of consumption in which the lesion is discrete and does not produce much solidification.

The second variety, the diffuse, for the purpose in hand included all cases in which the lesion is such as to solidify considerable portions of the lung in mass. Certain cases of Delafield's second division of chronic miliary tuberculosis were for convenience embraced in it, just as certain lesions much more complex than simple tubercular inflammation were embraced in the first form.

In the discrete form the nodules, varying in size, were separated by lung tissue which was physically normal or emphysematous. When in advanced cases cavities resulted from the breaking down of the nodules, they were usually of small size; and solidification of a portion of the lung, resulting from the increasing number of nodules, occurred only late in the course of the disease. There were usually more or less bronchitis and pleurisy, and also some emphysema of the kind known as compensatory. He believed that dilatation of the air vesicles and passages was caused by mechanical air distension; and it seemed very probable that the elasticity of a larger or smaller part of the pulmonary parenchyma was destroyed by the growth of new tissue if the thoracic expansion caused a negative pressure in the parts not affected which was greater than normal.

In the diffuse form the important clinical facts were, that consolidation occurred and produced, at a much earlier stage than in the discrete, recognizable physical signs, and that, in at least a large number of cases, the physical signs corresponded pretty closely to the patient's actual condition. The consolidation always, in his opinion, accompanied tubercular deposit, and the latter was always, as he also believed, the result of the growth of Koch's bacilli. The consolidated tissue sometimes consisted entirely of dense connective tissue. Sometimes patches of coagulation necrosis, diffuse tubercle, interstitial pneumonia, broncho-pneumonia, and peri-bronchitis were mixed in varying proportions in it. With this, as with the discrete form, there were usually bronchitis and pleurisy.

The clinical value of the classification temporarily adopted was that it recognizes the existence of cases in which the physical signs have no relation to the extent of the lesion; cases, moreover in which the bacillus is very likely not to be found at early date in the sputa. The discrete form furnished cases which were liable to be mistaken for primary tubercular disease of the larynx, for broncho-pneumonia, or for substantive emphysema. It had been his observation that in every case properly examined the tubercle bacillus has sooner or later been found; but in the meanwhile the diagnosis has often remained in doubt, and the discovery of the true nature of the disease has not infrequently come too late. In the diffuse form on the other hand, not only were the physical signs generally well-marked, but the bacilli were apt to appear in the sputa at an earlier date, and also to be more abundant from the first.

Having described a supposititious case in which the physical signs were doubtful and the sputum scanty or absent, so that the bacilli were discharged in small numbers, if at all, he said that such cases were not rare, and the recognition of this fact served to emphasize what was probably the most important point in connection with early diagnosis, namely: both physical signs and the negative evidence of the microscope are to be regarded only after careful study of the clinical history. Percussion, auscultation and the microscopic examination might reveal nothing; yet commencing consumption might be safely assumed to exist from the evidence of the patient's history and general appearance. The idea which he wished to convey was that cases may occur, and that not infrequently, in which tubercle bacilli cannot be discovered and in which physical examination of the chest gives no abnormal signs, or very vague ones; yet in which it is the phy-

sician's duty to make the diagnosis of consumption and to take proper measures for treatment, no matter at what cost. In the class of cases under consideration the chances of consumption being the trouble were so strong that the physician should risk his own reputation and perhaps put the patient to great inconvenience and pecuniary loss in order to save the life of the latter.

In speaking of the relation of the anatomical conditions to the physical signs he said that in the discrete lesion there might be nothing abnormal about the lungs except a few, small scattered nodules at, or near, one apex. In the great majority of cases, however, pleural adhesions existed from a very early period. With the few scattered nodules alone, there would, as a rule, either be no physical signs or these would be very vague and untrustworthy. The presence of pleural adhesions sometimes gave rise to special signs and sometimes did not. In certain cases it seemed quite possible that they caused the so-called "cog-wheel" or wavy respiration; and in others they might perhaps produce fine, dry or moist rales. Sometimes also they seemed to produce friction, stretching or tearing sounds. In early cases the adhesions were so often near the summit of the lung (where relatively little gliding motion of the pleura took place) that it was easy to understand how frequently it was impossible to demonstrate their existence during life.

It was not clear to him, however, why many signs attributed by a number of observers to pleuritic adhesions should really be caused by them. Why, for instance, the type of subcrepitant rale, sounding like the bursting of fine bubbles, should ever be produced by the stretching of tissue, moist or dry, it was difficult to explain. It was easy to say, and it at first seemed plausible, that an increase of serum in the pleural adhesions would produce this sound; but we did not positively know that this condition ever did actually give rise to it. Having spoken of the mechanical results of pleural adhesions, so far as the lung and chest movements were concerned, he said that in spite of very widely distributed and firm adhesions, it was possible for a lung seemingly to do its work as well as usual, and no symptoms whatever might indicate firm union between the pleural surfaces over the entire lung.

If, in addition to the nodules, there was enough bronchitis, signs of this alone might be found. Signs of bronchitis, with or without emphysema, upon one side of the chest could, as a rule, be regarded as valuable evidence of consumption, since bronchitis confined to one side probably occurred unless there was some local cause. When the nodules became sufficiently numerous to crowd one another pretty closely the lung was practically solidified, and the signs became those of consolidation. In such instances, however, the disease was far advanced. It was evident that in this form the physical signs bore but little relation to the extent of the lesion. The diagnosis in early cases must be made without too much regard for the signs, and the same was true of the prognosis also. In the absence of bacilli from the sputa the patient's general condition and history must be the main guide.

DR. J. S. ELY related the case of a woman at the Roosevelt Dispensary in which the physical signs were entirely negative, but in which he was led to make the diagnosis of chronic miliary tuberculosis from the progressive emaciation and general appearance of the

patient. It was impossible for her to leave the city, but under treatment she steadily gained in weight and strength. About six weeks ago she was attacked with a severe pain in the left eye, but Dr. Ely could not detect any trouble about the organ. Dr. Weeks, however, to whom she was referred for examination, discovered four or five miliary tubercles far down on the edge of the retina; thus confirming the diagnosis made. It seemed to him that the early diagnosis of tubercular disease of the lungs had come to assume a specially important aspect in view of the now very generally recognized fact that many cases could be cured if they were taken in time. It was often said that Koch's discovery had added nothing to our knowledge of the treatment of phthisis; but there could be no possible doubt that it had already been of great practical service. The results of the experiments made by Dr. Trudeau on rabbits, he thought, were of the greatest possible value in this connection. While all the rabbits inoculated with tubercular virus which were confined in an unhealthy environment died, only one of the inoculated animals which were given the best possible environment died. An examination of the lungs of the rabbits which recovered showed that the tubercles had become encapsulated, and were thus rendered incapable of doing any further harm. In the light of such results it could readily be seen that it was of vital importance that we should be able to recognize the presence of the disease at the earliest possible moment.

Dr. F. W. JACKSON related, by way of contrast, a case directly the opposite of Dr. Ely's, in which the patient presented the appearance of more than ordinarily robust health, and gave no history of anything like phthisis; and yet in one of her lungs, to his great surprise, he found a cavity. Afterward the patient's health gradually broke down, and the other lung became involved also. While, therefore, in some cases we had to make the diagnosis without the aid of physical signs, in others, on the contrary, the diagnosis had to be made from the physical signs alone.

His observations had led him to believe that pleural adhesions were very frequently present without giving rise to any physical signs, and he thought this was not generally recognized. Another point not sufficiently appreciated to which he desired to direct attention, was the fact that râles, due to whatever cause, were not constant. Thus they might disappear and reappear while the patient was actually under examination. Two lessons might be drawn from this circumstance. In the first place, it should teach us charity to our neighbors, as it would explain the reason why a râle heard by one auscultator sometimes could not be detected by another. In the second place, we might learn from it that a single examination was not sufficient to furnish a clear diagnosis.

Dr. E. V. AGRAMONTÉ said that he regretted that Dr. Roosevelt had not said more about the subject of prognosis, since there were a considerable number of cases of phthisis which seemed to recover.

Dr. ROOSEVELT said that he had been obliged to omit a portion of his paper relating to the matter of prognosis. While the statement made by Dr. Flint some years ago that about fifty per cent. of all cases of phthisis recover was no doubt strictly true, he thought that it had been productive of considerable harm by encouraging physicians to take a more hopeful view of the disease than they ought. The statement was based

on the fact that so many cases of cured pulmonary tuberculosis were found in the dead-house; but it was to be remembered that such an estimate would, by no means, apply to the consumptive patients who come to us for treatment.

DR. MAX EINHORN read a paper entitled,

DEMONSTRATION OF A NEW METHOD OF OBTAINING SMALL QUANTITIES OF STOMACH CONTENTS FOR DIAGNOSTIC PURPOSES.

After referring to various devices which had been suggested as a substitute for the stomach-tube, the use of which it was especially desirable to avoid if the presence of an ulcer was suspected, he described and exhibited upon three patients a new method of his own for obtaining small quantities of stomach contents. The instrument he employs is a hollow oval vessel made of silver, one and three-quarters centimeters long, and three-quarters of a centimeter wide, and having a narrow opening at the top. In introducing it the operator carries it to the back of the pharynx near the root of the tongue, and then instructs the patient to swallow. To the vessel is attached a thread in which a knot is tied at a distance of about forty centimeters from the vessel, so that it can be known when the latter reaches the stomach. It usually takes about five minutes for it to pass down through the oesophagus. In case much mucus is likely to get into it before it reaches the stomach, from a catarrhal condition of the upper air-passages or the oesophagus, it can be carried by a gelatine capsule which will be dissolved in the stomach. With this instrument Dr. Einhorn said they were able to ascertain (1) the permeability of the oesophagus; (2) whether the cardiac orifice of the stomach is clear or not; and (3) the contractions of the stomach, as indicated by the drawing-in of the thread.

Recent Literature.

Saunders' Question-Compendia, No. 5. Essentials of Obstetrics, arranged in the form of questions and answers. By W. E. ASHTON, M.D. Philadelphia: W. B. Saunders. 1890.

This manual is intended to assist students in mastering the essentials of obstetrics, and is based on the standard works of the day. As the book has reached its fourth thousand, its use has doubtless proved advantageous: being arranged in the form of questions and answers, it must be a convenient means of testing the students' knowledge while preparing for final examination. It is unfortunate that the new obstetric nomenclature has not been employed; to one already accustomed to the new methods of designating fetal positions, the nomenclature of this manual, especially of face and shoulder presentations, must be inconvenient and perplexing.

Electricity in the Diseases of Women. By G. BELTON MASSEY, M.D. Second edition, revised and enlarged. Philadelphia and London: F. A. Davis. 1890.

It is only a few months since we noticed the first edition of this little book; and it is only necessary to add now that we consider it the best treatise on this subject we have seen, and that the improvements introduced into this edition make it more valuable still.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, AUGUST 28, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

283 WASHINGTON STREET, BOSTON, MASS.**

THE FUNCTIONS OF STATE BOARDS OF HEALTH.

In the year 1849 a commission was appointed by the Legislature of Massachusetts to report upon a plan for "a sanitary survey of the State, together with a statement of such facts and suggestions as they may think proper."

The report of this commission, made in the following year, was in every particular a model of excellence, and as a comprehensive and far-sighted report has served as a guide for very much of the sanitary legislation which has followed. Among the important recommendations of the Commission was the following: "We recommend that a *general Board of Health* be established which shall be charged with the general execution of the laws of the State relating to the enumeration, the vital statistics, and the public health of the inhabitants."

It was not, however, until twenty years afterward that the Legislature of 1869 carried these recommendations into effect, and established the State Board of Health by law. The wisdom of this measure has been apparent year by year, as new and important duties have been entrusted to the Board.

Among the important functions of the Board, as defined by law, are the following: "To take cognizance of the interests of health and life among the citizens of the Commonwealth; to make sanitary investigations in respect to the causes of disease, and especially of epidemics, and the sources of mortality, and the effects of localities, employments, conditions and circumstances, on the public health, and to gather such information upon these matters as it may deem proper for diffusion among the people." To these general duties have been added in later years the general supervision of food-inspection and the over-sight of public water-supplies, etc. In the succeeding years since the creation of the Board other States have followed the example of Massachusetts, until nearly every important State now has an active board of health. In some States, notably in Illinois, the Reg-

ulation of Medical Practice has also been entrusted to the State Board of Health.

How well these numerous bodies have performed the functions assigned to them, is shown by the numerous excellent reports which have been published.

It might reasonably be supposed that the wide fields of the Western States should furnish abundant material for sanitary inquiry, and such is the case; but there are some noted exceptions in the material presented for the reader who is in quest of advice upon matters pertaining to preventive medicine, as the following extracts will show.

In the Report of the State Board of Health of — for the present year appears the following:

"**THE Tipton County Twins.** — Through the courtesy of Dr. — we are enabled to present a cut of a monstrosity, girl babies born to — and wife, of — on the 24th of June last. They are now being placed on exhibition in the large cities of the country."

Then follow three full-page illustrations of this infant monstrosity together with a full discussion of the important *sanitary and hygienic* questions as to "whether the legs on one side belong to one child, or does one leg on each side belong to each child?"

This piece of information would be interesting in its proper place, but that a body of gentlemen known as a State Board of Health should appropriate the public funds to the publication of such material is incomprehensible. The same report has the following alarming statement, or estimate as to the suicides, and this in a State of about the same population as Massachusetts. It is estimated that "the suicides in 1889 in this State were 900, far more than were caused by those bugbear typhoid fever or cholera infantum, and surpassed by only the diseases, phthisis and pneumonia. The attempted suicides are estimated at 4,725 cases, or if we apply to the whole State the dispensary average of fatalities to attempts as *one in twenty*, we would have a grand total of 18,000 cases!"¹ This marvellous statistician very cautiously adds, "but figures will lie, and I hope my ingenious imaginary ones do."

The following bit of useful information also is published in the monthly Bulletin of another State Board of Health:

"**CHewing GUM A HEALTHFUL EXERCISE.** — We have seen the most excitable young lad with a highly-strung nervous organization under his maturing influence, become a quiet and contented as the well-fed cow that lies in the barnyard chewing its cud. We know of nothing that will, with anything like such indomitableness (*sic.*) endure so much mastication. We have chewed a piece of this gum contentedly for two hours without any perceptible change in its bulk, and after remaining under the seat of the chair, on the under side of the table, or on the bed-post over night, if not found and confiscated, it was ready for as grand service as when first pressed between the molars.

"We believe that every ship sailing upon the high seas should be well supplied with chewing-gum; and in time of danger of shipwreck the passengers should be furnished with at least a half-dozen pieces, so that if cast upon some barren and uninhabitable coast or island, they might have something with which to beguile the weary hours; and we know of nothing so innocently beguiling."

What need of wasting time in the investigation of infectious diseases and their causes, and the prevention of pollution of water-supplies, when such useful fields of inquiry are presented as the foregoing?

¹ The entire number of suicides in England, with a population of 30,000,000, is less than 2,500 in a year.

CHEMICAL ALTERATIONS OF THE GASTRIC JUICE IN ACUTE AND CHRONIC MALADIES.

THE condition of the gastric juice during febrile states has been studied of late by Wolfram.¹ In the acute pyrexias which included a case of exanthematic typhus, two of intermittent fever, four of typhoid fever, six of pneumonia, the gastric juice, though containing pepsin, showed not the least trace of hydrochloric acid. In several chronic cases, including one of double fibrinous pleurisy lasting two months, and one of phthisis-pulmonalis, the gastric juice was normal. Uffelman and others, on the contrary, claim to have seen cases where the fever was not accompanied with absence of hydrochloric acid in the gastric secretion.²

The alterations in the gastric juice in phthisis have been studied, particularly in Germany, by Hildebrand, Rosenthal, Klempener, Immermann and others. According to Hildebrand, the normal acid is wanting when there is continued fever, while it is always present when there is no elevation of temperature. Brieger's observations agree in the main with these results—the acid was wanting in nineteen out of thirty-one cases. At the end of the disease there was present gastritis, with atrophy of the glands.

Rosenthal found that, whether in the earlier or later stages, the gastric juice of phthisical patients was generally devoid of free hydrochloric acid.

Klempener distinguishes the initial from the terminal dyspepsia. There is beside a pretubercular dyspepsia, in which the secretory activity is normal. In the initial dyspepsia, Klempener affirms that there is generally *hydrochloric hyper-acidity*. In the final stages he has found the hydrochloric acid deficient or wanting, and the processes of fermentation very much developed. He believes these latter phenomena to be the expression of a sub-acute or chronic gastritis.

In fifteen cases, Einhorn found the natural acid wanting in two cases, intermittent in one, and constant in twelve.

According to Shetty, there is always hydrochloric acid in the gastric juice in phthisis; sometimes this acid is in excess.

To sum up: It will be seen that there is nothing constant relative to the proportion of hydrochloric acid in the gastric juice of phthisical patients; in febrile cases the acid is generally found wanting; in the afebrile it may exist in the normal quantity or even be in excess.

Chelmonsky has in several cases noted absence of hydrochloric acid and diminution of pepsin in emphysema; he has frequently found this acid absent in the course of chronic phthisis.

In anæmia and chlorosis, Riegel observed the proportion of hydrochloric acid to be higher than the normal in three carefully-studied cases, and Ritter and Hirsch have claimed similar results from their rather incomplete analyses.

¹ Deutsche Arch. f. Klin. Med., t. xlii, p. 481. Cheron, in Bull. gen. de ther., t. exviii, p. 321.

² Cheron, loc. cit. (We have drawn largely from this article.)

Hayem, in cases of chlorosis, has found the digestive operations to be sometimes normal, and sometimes profoundly altered; in the latter cases there was deficiency of hydrochloric acid, with dilatation of the stomach. In no case did Hayem find hydrochloric excess.

Georges has noted hydrochloric deficiency in the anæmic patients whose gastric secretions he has examined, while the organic acids existed in large proportion.

In a case of grave anæmia consecutive to hemorrhages, Lyon found absence of hydrochloric acid.

In diseases of the heart, according to Hüller, whether the affection be valvular or muscular, the consecutive circulatory stasis, even when it is little pronounced, suffices to enfeeble or even to destroy the power of the stomach to fabricate acids. Of ten patients, nine had hydrochloric deficiency.

Sandberg and Professor Lée have also noticed absence of hydrochloric acid in cardiac affections.

According to Einhorn and Ewald, the hydrochloric acid only disappears in cardiac patients when there is a catarrhal gastritis.

Want of hydrochloric acid in the gastric juice has been found in diabetes, gout, uremia, progressive pernicious anæmia, and in Addison's disease.

According to Bourget and Georges, there is always enough pepsin, or at least of pepsinogenous substance in the stomach. These writers do not believe in the remedial properties of this ferment, when therapeutically administered, and here they indicate a divergence from a considerable clinical experience, which attests to the efficacy of artificial pepsin in many digestive disorders.

MEDICAL NOTES.

— Cholera is reported as quite prevalent in many parts of Japan. In Nagasaki the number of new cases at time of mail advices (July 29th) were one hundred a day, and the deaths forty-five per day. In Tokio the disease is but slightly prevalent as yet; but in Yokohama harbor, which is a great centre for shipping, a number of cases have appeared.

— Asiatic cholera now prevails on the Arabian shore of the Red Sea, in Cairo, at Baku and Nicolaeff, in Russia, and in several provinces of Spain. From Valencia the disease has been carried to several other coast provinces, to Madrid and across the country to the borders of Portugal. Cholera first appeared near Mecca this year on July 28th, and the daily mortality in Mecca and Cairo was several hundred a week later. At first the Egyptian Government sought to bar out the disease by preventing the return of the pilgrims northward, and the strictest quarantine was enforced, but, in all probability, the infection had passed before these precautions were taken, for there are cases of cholera in Cairo, and it is probable that there are cases at ports further westward on the southern shore of the Mediterranean.

— Dr. Junker, whose name is familiar to those who have followed the recent literature of African exploration, is said to have learned in Central Africa to relish fried ants, and lived for years on a negro bill-of-fare. He goes so far as to say that, in his opinion, the white man who accustoms himself to native food will keep in better health than if he enjoyed the best of European cookery. At first he viewed with positive repugnance a good deal of the food that was placed before him, but he soon learned to eat negro dishes with a good appetite. It was his rule of life in Africa to adapt himself as nearly as possible to native customs and usages, whether he was living among Arabs or negroes; and this practice saved him from many trials and perplexities when the resources he had brought from Europe were exhausted. Whether he recommends carrying conformity with native diet to the point of anthropophagy, is not stated.

— The equity suit between the officers of the Medico-Chirurgical Hospital of Philadelphia, and certain owners of property adjoining the site of the new building of the hospital, has been settled by mutual agreement. The bill in equity was entered on July 5th by the owners of property, to restrain the managers of the hospital from placing windows in the party walls of their new building, on the ground that they would be annoyed by the disagreeable sounds and sights. A survey of the premises shows that the old building, to which a story was to be added, was three inches over the party line, and that the new building was one and one-half inches over the line. Upon these facts being submitted the suit was stopped and a compromise arranged. It allows the managers of the hospital the privilege to put in immovable windows of translucent glass with movable panels of stained glass in the new building, and forces them to limit the inmates of the wards to patients in a convalescent condition.

— As a rule, the medical colleges in the South are not up to the ideal standard. For instance, in the annual announcement of the Medical College of Georgia this frank confession is made: "Our graduates may not be classed as scientific physicians; they may not be able to locate cerebral diseases with the accuracy with which the old phrenologists could place the mental faculties; their abdominal surgery may lack the boldness of Jack the Ripper; they may not distinguish the bacterium from the comma-bacillus, but they will in a few years be able to apply the resources of medical science and treat the peculiar diseases of their localities with a practical shrewdness which would astonish those of more ambitious training."

NEW YORK.

— New York physicians are very considerably interested to find that from this time onward it may be regarded as a misdemeanor for them to attend any of their patients who may reside in the neighboring State of New Jersey, or who may be taken ill while visiting there. At the recent session of the New Jersey Legislature a law was enacted which is now

operative, providing that every person practising medicine in the State must be accredited by a State Board of Examiners, before whom he or she must pass an examination in writing. No physician going into the State will be entitled to register with any board of health unless upon presentation of a certificate from the Examiners; and a board of health may refuse to accept a death certificate from any unregistered physician. The penalty for practising in the State without the authorization of the Board of Examiners is a fine of from \$50 to \$100, imprisonment for from ten to ninety days, or both.

According to the provisions of the law the Board is to consist of nine members, of whom five are to be of the regular school, three homeopaths, and one eclectic; and three vacancies to be filled will occur each year. Under a strict interpretation of this law a New York family at a New Jersey summer resort will not be able to summon a physician from New York without incurring the risk of exposing him to the penalties of its infringement. Dr. B. A. Watson, of Jersey City, has expressed the opinion, however, that the law was not intended to operate as stringently as its language might imply, and that any reputable New York physician going to visit a patient in New Jersey would not be molested.

Miscellany.

THE NEW SURGEON-GENERAL.

THE President has nominated Colonel Jedediah H. Baxter, chief medical purveyor of the army, to be surgeon-general with the rank of brigadier-general, in place of General Moore, retired at the age of sixty-four.

Dr. Baxter was born in Vermont, May 11, 1837, and is the son of the late Portus Baxter, for several years a Representative in Congress. He entered the army as surgeon of the Twelfth Massachusetts Regiment of Volunteers (Col. Fletcher Webster's) being mustered in on June 26, 1861. He has been in continuous service in the army from that time. He was promoted to be brigade-surgeon, United States Volunteers, April 17, 1862, and served with distinction in the Peninsular campaign with the Army of the Potomac. He was surgeon in charge of the United States General Hospital Campbell at Washington, one of the largest hospitals in the United States, from the time it was opened until January, 1864, when, at the request of General Fry, provost marshal-general, he was detailed on the latter's staff and assigned to duty as chief medical officer of his bureau. In that capacity Surgeon Baxter collected the records of the physical examinations of more than one million men who presented themselves for admission into the army and compiled therefrom an extensive work on vital statistics. At the close of the war, Surgeon Baxter was appointed assistant medical purveyor, with the rank of lieutenant-colonel, and was promoted to be chief medical purveyor by President Grant in 1872. Dr. Baxter is a graduate of the University of Vermont, from both the academic and medical branches of that institution.

THE NEW YORK FLOATING HOSPITAL.

THE New York *Times*, in a recent issue, contained an interesting sketch of the floating hospital in the harbor, maintained by the St. John's Guild, from which we subjoin some extracts:

"The barge leaves North River, foot of West Forty-fourth Street, at 8 A.M. Mondays and Thursdays, and East River Tuesdays and Fridays, so both the East side and West side sufferers may have equal benefits. Long before the hour for leaving the wharf the people begin to gather from all directions. The mothers and children are soon in as orderly lines as can be formed. The well-trained men and women of the Floating Hospital understand them and their needs, and treat them accordingly. The efficient 'doctor' stands on the gangplank to review and see the card of every one in that army of the great unwashed. He speaks several languages, and can talk to each woman in her own tongue. He carefully scans each comer. 'No contagious disease allowed on board,' is the health-saving mandate on the cards of invitation.

"The ones not very ill, simply ailing and suffering from the heat, go on the upper deck of the barge. The sick ones, mothers or children, stay on the lower deck; they have the privilege of going to the Seaside Hospital, on the south side of Staten Island. This hospital is under the same management as that of the Floating Hospital. The barge is moored midstream when nearly opposite the Seaside Hospital. A certain number of flags are on its flagstaff. From these the captain of the barge learns how many vacant beds there are, and how many women and children can be accommodated. Rowboats are lowered, and squads of women and children, with their bundles, are lowered into the boats.

"Those that go to the Seaside Hospital are received by a pleasant-faced matron. They are registered and assigned to their wards. Three trained nurses and two doctors attend to the needs of the patients. It is a great treat for these poor women to spend from two to ten days amid such clean, pleasant surroundings. They have good, plain food, well-cooked and neatly served. They can bathe in the salt water. A sandy beach is near the hospital. They can walk or sit or sew in the grateful shade of a grove of cedars in the rear of the building. They are expected to wash their own garments — some of them have none to speak of. The laundry is conveniently near, and they can absorb practical ideas about cleanliness. The contrast between the outgoing and incoming recruits of the hospital is gratifying to the beholder.

"The vast crowd on the Floating Hospital fare well. Milk is furnished twice a day for the young children. The policemen form them in line. They each have a milk ticket and a cup or pickle bottle, or most likely a whiskey bottle, which is handed over to the patient genii of the big milk kettles, who fill the receptacles with good, pure milk. A warm meal is given on board the barge at high noon to the adults and children. Three hundred places are set for them, and reset three times over. They come in battalions of three hundred down the stairs, guided by the policemen, so in their haste they will not stumble on their neighbors or crush them.

"A host do not wash themselves, and of course cannot be expected to wash their garments. This omis-

sion is provided for as far as the children are concerned. The doctor of the Floating Hospital gives bath tickets to children who want them. They come in files of ten to the woman who superintends their bathing. She has five bath-tubs big enough to hold two water nymphs — one at the upper end and one at the lower. She washes them all so systematically that she bathes between eighty-two and ninety during a day. This is the only bath some of them ever get."

THE TREATMENT OF CYSTITIS IN WOMEN.

THE following is an abstract of a paper written for the Obstetric Section of the Berlin International Medical Congress by Thomas More Madden, M.D., F.R.C.S.(Ed.)

"Of all the diseases which come before us in gynaecological practice there is none more frequently met with, more distressing in its effects, or more intractable to the means generally relied on for its relief than cystitis in women. I therefore desire to bring under the notice of the International Medical Congress a method of treatment which I have found, by clinical experience, to be generally successful in the rapid curative treatment of this condition. The measures most commonly employed in such cases are merely palliative, and may relieve but *per se* can never cure well-established cystitis in women. Nor am I aware of any method by which that can be accomplished save by giving the bladder absolute physiological rest. For this purpose Dr. Emmet's operation, that is, the establishment of an artificial vesico-vaginal fistula, may be successfully employed in some instances, but the practical objections to it are so great and obvious that for several years past I have abandoned this procedure in favor of another which I have found more generally effectual, and quite free from the disadvantages of the operation referred to. The plan which I have now employed in a very large number of cases of cystitis in the gynaecological wards of the Mater Misericordie Hospital, Dublin, consists firstly in the full dilatation of the urethral canal with the instrument exhibited, so as to paralyze the contractility of the sphincter vesicae and canal, and thus produce a temporary incontinence of urine; and secondly, in the direct application through the same instrument of glycerine of carbolic acid to the diseased endo-vesical mucous membrane. I may add that any pain thus caused may be prevented by the previous topical application of a solution of cocaine, and that the procedure recommended seldom requires to be repeated more than once or twice at intervals of a week or ten days; and combined with the internal use of boric acid, rarely fails to effect a rapid cure in any ordinary case of female cystitis."

PAROXYSMAL PULMONARY EDEMA IN CHRONIC ALBUMINURIA.

PULMONARY edema in cases of chronic renal disease is an important factor, and Professor Bouvieret, of Lyons (*Revue de Méd.*, pp. 241-251, 1890, and *Practitioner*, August, 1890), is anxious to call attention to a paroxysmal form which seems to him, though rare, not to have received sufficient attention. The characteristic symptoms are a rapid onset of dyspnoea, with a very abundant albuminous expectoration.

Such attacks recur rapidly, ending either in death or in sudden and complete relief. Dr. Bouveret has met with only two cases; both of them in patients with chronic interstitial nephritis. In the first, a man, aged sixty-two, who had long-standing granular kidney, the dyspnoea was very severe, though irregular, for four days before death. The tension of the radial pulse was very high throughout. The sputa amounted to about three pints *per diem* of a frothy and highly albuminous liquid, with occasionally a trace of blood in it. Patient was bled and cupped, and treated with strong hydragogue purgatives, but died in asphyxia, at a temperature of 104.2°. The necropsy showed much destruction of the cortical tissue of the kidneys of old standing, extreme cardiac hypertrophy and dilatation, and a remarkably abundant oedema of the lungs, with no broncho-pneumonia. In the second case, a man, aged forty-five, there were in two years three crises of dyspnoea, and abundant albuminous expectoration, followed in each instance by a rally. In the last and most violent crisis, which came on very suddenly, and without apparent reason, when he was going to bed, and lasted only four hours, he coughed up about three pints of fluid. The day after the attack he felt strong enough to get up and do some work. He was probably in an early stage of contracting interstitial nephritis. At the times of dyspnoea and abundant expectoration very little urine, and that of high specific gravity, was passed; at the other times it was abundant and of low specific gravity. His heart was not much hypertrophied, and its valves were efficient. Fränzel, in discussing similar symptoms, inclined to attribute them to a loss of equilibrium of energy between the right and left ventricles; the left ventricle in fact giving way suddenly under its constant heavy work. That is a view supported by Dr. Welch, but quite inconsistent with the high arterial tension in the first case mentioned, and with the normal tension and very slight cardiac hypertrophy in the second case. Professor Bouveret is inclined to suspect a vaso-motor paralysis of the pulmonary arterioles, though he admits he cannot point to the nervous origin of this vaso-motor paralysis. He advocates a treatment by bleeding, dry cupping, poulticing the thorax, and administration of hydragogue purgatives and alcohol in large doses; in extreme cases of cardiac failure, subcutaneous injection of caffeine and ether. In the first case such treatment was adopted without success.

Correspondence.

[From our Special Correspondents.]

LETTERS FROM THE BERLIN CONGRESS.

BERLIN, August 6, 1890.

MR. EDITOR:—Truly American midsummer weather greeted the stream of doctors which poured into Berlin during the latter part of last week, and made, at any rate, our countrymen feel at home, even if unpleasantly so. Fortunately there is here no *costume de rigueur*, and all except our English *confrères* promptly exchanged their silk hats and thick black coats for more comfortable garments. "Doctors, doctors, everywhere; and all sorts of things to drink!" were the first impressions of the newly arrived. The corridors of all the principal hotels were filled by the learned-looking gentlemen—of all nations, of all ages and sizes, from the renowned aged professors to the recently

graduated American medical students enjoying that blissful period of absence of responsibility and the pleasures of European life before taking the fatal plunge into the hateful office chair and contemplation at home. Familiar faces were seen on all sides.

Monday morning found the foreign members, for the most part, in a state of hopeless confusion as to what was to take place, and where to search for light. In a lamblike procession they entered the doors of the central bureau in the Leipziger Strasse, and were there furnished with members' cards and programmes, and with these in their hands flocked in *droschkas* to the Circus Rentz, to the first general meeting of the Congress. Arrived there, they learned that, instead of three or four thousand delegates, there were between five and six thousand, and more to come. Many of the men had sent word of their intention to attend the Congress but a short time before its opening, and a considerable number of papers were sent in at the last minute. These two facts threw such an unexpected load of work upon the executive committee that, of necessity, it was impossible to dispose of it all as smoothly as would have been the case with a less unwieldy body.

One very excellent feature of arrangement was that of a "Committee for Lodgings," which did much to mitigate the discomforts which would else have arisen from the crowded condition of the hotels.

When, at last, the great assembly was seated in the Circus Rentz on Monday morning, it was addressed by its president, the renowned Professor Virchow, whom Time seems to have forgotten, so little is he changed in fifteen years; and the Congress was formally opened. A statement by the Secretary, Dr. Lassar, that there were 140 French members and 630 Americans, called forth loud applause.

The sessions of the separate sections were, for the most part, held in the various rooms of the great *Landes Ausstellung* building. On entering the grounds in which it stands, we were directed to a small building on one side, in which was a bureau of general information, where one obtained programmes, lists of members, and a journal of proceedings, issued daily. By the latter we were informed as to the papers to be read in the different sections, places of meeting, hours, etc. Unfortunately, the information was frequently incorrect. As, for example, in one copy of the journal it was announced that Billroth would read upon "Operations for Cancer of the Stomach," at 3.30 p. m., in the *Landes Ausstellung*, in the Surgical Section. He presented his paper at ten that morning, and there was no afternoon session at all. Again, Dr. Keen, of Philadelphia, was announced to read upon "The Surgery of the Lateral Ventrices," one morning, and after two days of waiting, was called upon when he had not been announced at all.

These annoying *contretemps* were frequent. The number of men, the size of the rooms, and the noise of coming and going also, in the larger sections, made it impossible for any but those in the front row to hear anything.

One of the most interesting debates in the Surgical Section was upon "The Operative Treatment of Rectal Cancer." Professors König, Czerny, Lange (of New York), advocated extensive resections, and Mr. Bryant (of London) lumbar colotomy, in preference.

On the third day, the Surgical meetings were transferred to the amphitheatre of von Bergmann's clinic, and became much more satisfactory, owing to better acoustics and ventilation. This meeting was presided over by Professor Lister. There Schede (of Hamburg) showed, in patients and by photographs, some admirable and striking results of his extensive rib resections for empyema. Ziegler also showed a patient in whom he had extirpated the larynx two years ago for carcinoma, who had had no recurrence, and who could speak plainly.

MacEwen (of Glasgow) read before the Orthopedic Section an able paper on "Osteotomies," and was one of the most striking personalities of the Congress.

The single communication which called forth the most enthusiasm was that of Professor Horsley before the Neurological Section, on "The Innervation of the Larynx."

Perhaps the most satisfactory feature of the Congress was the exhibition of surgical apparatus, instruments, antisepsics, etc., which was very complete, and contained much that was new and of value to be seen. Pyoktanin (the new antiseptic) dressings were shown. Various forms of operating-tables were exhibited, the best feature of which was that of a heavy, solid rubber covering, easily cleaned. The tables on wheel-feet, with glass sides and tops, and light iron frames, for carrying instruments and dressings in the wards and amphitheatre, were also excellent.

The most remarkable surgical (one is tempted to say eccentricity) performance shown in the whole Congress was that of Professor Gluck of Berlin, who presented several patients whose knee and elbow joints he had excised, and thereafter substituted ivory joints instead. The patient upon whom this singular essay had been longest under trial was one upon whom the operation dated three months back. In two instances the professor had succeeded in giving the patients moderately movable joints, but in no case were the wounds fully healed and free from suppuration. And in one from whom he had subsequently removed one of his ivory joints after it had been worn for some time, on account of local trouble to which it gave rise, the ivory was seen to be partly eroded, as though beginning to be absorbed. This surgical experiment was viewed with decided scepticism as to its ultimate success by the majority of those who saw it, while, nevertheless, they appreciated the cleverness of the feat.

The social features of the Congress were manifold and varied. Many private houses were thrown open to the wives and families of the members, numerous small and very delightful receptions taking place in this way, which were a great boon to the ladies, who were of necessity left to their own devices during many hours of the day.

Of the public entertainments, that of the Bürgermeister and city officials at the Rathaus was the most notable and least fortunate. To say that during the better part of the night boisterous good-fellowship reigned supreme amongst the three thousand men who attended the festivity, is perhaps to express its character as mildly as is consistent with the facts.

On Wednesday evening the various Sections dined at the different hotels. The Surgical Section, to the number of more than seven hundred, assembled at the great hall of the Central Hotel. Von Bergmann presided, on his right Prince Carl Ludwig of Bavaria, on his left Sir Joseph Lister. Amongst the guests at the president's table sat Sir James Paget, Bardleben, Dr. Billings, Sir William McCor-
mac, Von Esmarch, Dr. LeFort, Péan, Bilroth, Mr. Bryant, and some thirty others. A full orchestra drowned all other sounds. The speeches were made between the courses, a most wise provision for occupying the long intervals. All the German speakers took care to be especially complimentary to their French *confrères*, which of course was to be expected. The only name whose mention called forth general applause was that of Lister, who, as the father of antiseptic surgery, received hearty recognition.

At the dinner on the same evening of the Section of Clinical Medicine, the most noteworthy speech was that of the Italian Bacelli, who, with all an Italian's oratorical power and grace, delivered a speech in three languages, gliding gracefully from Latin to Italian and finally French with most consummate art, and a delivery worthy of Salvini.

On Friday and Saturday the exodus began, and by Sunday morning but few of the foreign members remained.

And so ended the greatest of the International Congresses up to the present time, though in the opinion of many by no means the most satisfactory. The management was freely criticised, and it certainly left much to be desired; but it should be taken into account that nearly twice the number of men attended the Congress that was expected; and it was perhaps too much to ask of any committee, under the circumstances, that all should go smoothly with so unwieldy a body. The mere seeing and hearing so many of the greatest masters of the profession was in itself of much value. And the published proceedings will later

give ample evidence of the quantity of work of the highest order that was presented.

For the gratification of our pride in our own national surgery, it was to be noted, that, although happily we had much to learn from our *confrères* here, we can also feel that we are in most matters quite abreast of them, and excel in some.

—————

BERLIN, August 9, 1890.

MR. EDITOR: — At the close of the Tenth International Medical Congress, I send a very brief statement of some of the interesting features of this, in many respects, most noteworthy of all medical congresses hitherto held. The official register of names states that there were 5,737 members. These were accompanied by more than 1,000 ladies; while, in addition, 143 persons were registered as taking part in the Congress, although not as actual members. Berlin has opened its doors to this large assemblage of strangers, and the citizens have received into their homes those whom the hotels could not admit. Of the foreign members of the Congress, the largest number, 659, came from the United States; 429 were from Russia, 358 from Great Britain, and 179 from France. It was feared, until the last moment, that the French would find it impossible to so far forget national strife as to join in the amicable pursuit of science — science, which knows no limits of time or space or peoples.

It is impossible to give any accurate information of the amount of work which has been done. The member interested in the work of any given section would find all his time occupied in listening to the papers and discussions, and in witnessing the demonstrations given by members of his own section.

As an illustration of the work of the sections, brief mention may be made of some of the points of interest in that relating to pathology and pathological anatomy. This was practically under the guidance of Professor v. Recklinghausen, although changes were regularly made in the chairmanship to compliment the many distinguished members from various countries. There were three general topics which were discussed. The first concerned the part taken by leucocytes in the new formation of tissues; the second related to the disturbances of the myocardium; and the third embraced the subject of tuberculosis.

It was especially noteworthy to see the practical agreement of such distinguished investigators as Ziegler, Grawitz and Marchand, in denying any active participation of the leucocytes in the new formation of tissues, in consequence of existing pathological processes. Ziegler, in particular, who had been most diligent in claiming such active participation, gave up his position in the most positive manner. Virchow, who was present during a part of this discussion, would have been more than human had he not derived a certain satisfaction from seeing so complete a refutation of some of the theories which had arisen in opposition to some of the theses he had defended during a period of many years.

The question of a segmentary myocarditis, which has been lately brought forward, especially by Renaut, found its strongest opponent in Recklinghausen, who was enabled to show that the disassociation of the muscular fibre of the heart might occur during the death-agony in certain cases of death from violence, and that there was no proof of its occurrence before this period.

Our knowledge of the method of origin and extension of tuberculosis was ably presented by Ponfick, and there was a conspicuous harmony in the views on this subject which were presented by the various participants in the discussion. While there was nothing essentially new or novel in the consideration of the pathology or pathological anatomy of this subject, at the first general meeting of the Congress a most startling communication was made, one which, if it proves true and applicable to human beings, will be universally recognized as the most important contribution ever made to practical medicine, with the single exception, perhaps, of anaesthesia. Robert Koch announced in his paper

on "Bacteriological Research," that he had been able to prevent the death of guinea-pigs and rabbits after inoculating them with pure cultures of tubercle-bacilli, by appropriate treatment. He gave no detailed statement of the nature of his experiments or of the medicines employed, as his work was not entirely completed; but it is whispered that the drug he has found so efficient is a salt of cobalt. When it is considered that guinea-pigs are, perhaps, the most susceptible of all animals to the ravages of the bacillus tuberculosis, and that Koch is one of the most cautious of all investigators, one who may be said to have never made a mistake nor been obliged to retract a word of his statements, the significance of this preliminary communication may be appreciated. It is well known that he has for years been searching for the possibility of a cure for tuberculosis, and the statements he has just made are the outcome of these years of work. From any lesser light they would be incredible, even impossible; from him they are full of such promise as to be almost blinding.

I will say nothing of the other important papers presented at the general meeting of the Congress, where we were so ably represented by Wood, of Philadelphia; nor of the distinguished hospitality of the empire, the refined courtesy of the empress, the unbounded generosity of the city, and the warmth of the welcome extended to the coming guest, as well as the liberality which was given at the spending of those who were parting.

The one spirit which dominated the entire Congress, which ruled its greatest as well as its minutest affairs, was to be found in the man whom the nations of the world, through their medical representatives, assembled to honor and give homage to — Rudolf Virchow.

BERLIN, August 10, 1890.

MR. EDITOR: — The Tenth International Medical Congress has been a very successful and interesting one. The assemblage has included a great number of distinguished persons, and everything has been done which energy, forethought and unboundded hospitality could accomplish, to render the sojourn of the foreign guests both pleasant and profitable. It is interesting to note that some two hundred French delegates were present at the Congress, and that they were received with marked attention, both officially and privately. One of the most distinguished of the French delegates told me, on the last day of the Congress, that he and his countrymen were highly pleased with their reception and by the hospitality shown them, which had been far greater than they had expected, and that he thought that the incident would have a very salutary effect politically as well as professionally.

The whole number of members registered was over 5,700, besides 1,300 ladies, who belonged to the families of the members. Some 3,000 of the members were German, and about 700 were from the United States.

The meetings of the various Sections were held in the spacious halls of the Art Exhibition Building, which is situated in a park close to the Tiergarten, these being very convenient of access. It is needless to say that there were abundant opportunities for obtaining food and drink for those who were ever weary of purely scientific treats.

The only drawback to the perfection of the arrangements was the bad acoustic properties of the rooms, while the ease with which members could leave one Section to visit another was a disadvantage, inasmuch as an anxious and aimless thousand or so were always wandering about and disturbing those who were listening to the papers. As all of the latter were in a tongue foreign to many of the hearers, the best acoustics and closest attention were necessary for their full comprehension. The only other criticism that could be made, was that the members were worked too hard. Fifteen sessions of the Sections in six days, with three general sessions, were more than most men could endure; so that, finally, desertions became frequent. The weather, also, was hot and sultry on several of the days, much more so than is usually the case in Berlin.

Very complete arrangements were made for the recep-

tion and entertainment of the wives of the members of the Congress, so that they could visit the points of interest in and about Berlin while their husbands were attending to the meetings of the sections. To accomplish this a committee of the wives of the physicians of Berlin put their time and their homes at the disposition of the foreign ladies, so that, by excursions, receptions, and ladies' dinners, their guests were most hospitably and agreeably entertained. The city of Berlin also gave a great reception to the members of the Congress at City Hall, while the physicians of the city, on the last day of the congress, gave a festival and concert to the members and their wives at Krall's great garden. At both of these free refreshments were provided, including wine, on a most liberal scale. Five grand balls were also given simultaneously in as many different localities.

Besides all this, the most liberal hospitality was offered by the prominent physicians of Berlin connected with the different sections of the Congress, in the form of sumptuous dinners to prominent members of the profession from other cities. At these and at club dinners given by the Sections and by the special societies, and at the various entertainments already mentioned, the evenings were passed joyously, sometimes even hilariously, so that it was difficult to find all the participants at the opening of the Sections at 8 A. M., or at the operations performed in the hospitals promptly at 7, or even at 6.30 A. M.

Besides the Congress itself, with the work of its general sessions and various Sections, a very important adjunct was the Medical Scientific Exhibition, in which the professional and commercial interests were most happily and amicably combined. Instead of being regarded almost as intruders at a medical gathering, the manufacturers, chemists and publishers were welcomed as coadjutors and indispensable assistants of the profession. This exhibition was opened with great ceremony on the Saturday before the opening of the Congress. Professor Virchow in a happy speech pointed out the advantages which medicine derived from the kindred sciences here represented. Speeches were made by the representatives of the various countries who were present, and with cheers for the German Emperor and a crash of military music the exhibition was declared to be open.

Here were many interesting novelties which might well be found valuable at some of the exhibitions connected with medical meetings in our country. For instance, there were very elaborate series of pathological preparations, sent by the most eminent men and institutions in Germany, and representing various departments of medical knowledge. There were also collections of photographs and of wax figures illustrating various diseases, the collection representing maladies of the skin being especially noticeable. There were models of all parts of the human anatomy, and frozen sections preserved in alcohol, teaching admirably the anatomy of various pathological conditions and surgical operations. The frozen sections showing the pathology of the enlargement of the prostate, and the relations of the bladder and peritoneum in supra-pubic cystotomy, as well as the sections relating to obstetrical and gynaecological subjects, were of the greatest interest. There were complete models and drawings illustrating the methods of cremation. Models in wax showing all sorts of injuries received in murderous attacks were contributed by the medico-legal authorities. The dental exhibit even comprised very interesting specimens, showing the diseases of the teeth, and alveolar processes of elephants and other animals.

Together with the preparations mentioned above, there were complete exhibitions of instruments, goods, medicines, and chemicals, military and field hospitals and hospital appliances, all sorts of electrical and photographic apparatus, books, maps, etc.

A very interesting set of charts was exhibited by the Imperial Board of Health, showing the relative and absolute frequency of various diseases in different parts of Germany. One map also showed the number of doctors in comparison with the population in all parts of the empire. It may interest some readers to know that there are parts

of Eastern Prussia where there is only one physician to each 10,000 of the population.

It is quite impossible to enter into details in regard to the various exhibits. A catalogue of some three hundred pages served to explain them, and many of the members spent a great deal of time in the Medical Scientific Exhibition, which was honored by a prolonged visit of the Empress, and which is to be kept open for a week longer, on account of the great interest which it has excited.

In regard to the work of the Medical Congress itself, I will soon send you some very brief observations. It was opened with great pomp in the Circus Renz, which was packed almost to suffocation with a brilliant gathering of men eminent in the profession from all over the world. Behind the speaker's tribune rose a colossal figure of Easculapius, and opposite to it, on the other side of the great hall, was an enlarged copy of the Minerva Medica of the Capitol. Four hundred ladies graced the occasion with their presence, and in the imperial box sat the Bavarian

duchess whose husband is a physician and was a member of the Congress. The speeches of Virchow in German and Bacelli in Latin were the main events of the occasion. At the closing session in the same place the paper of Dr. Wood, of Philadelphia, on Anesthesia, excited great interest, not only on account of its scientific value, but also because it was so well delivered that it was easily understood by all who knew English even moderately well. (In general, other nations seem to find it much easier to understand the American than the English, a fact which is by no means strange.)

The next Congress is to be held in Rome in 1893, early in October. For this reason the speech of Bacelli excited great interest, and when, after a session lasting nearly six hours, Bacelli and Virchow, after exchanging felicitous compliments in elegant Latin, finally embraced and kissed each other, the Tenth International Medical Congress closed amid the greatest enthusiasm.

Respectfully, E. W. CUSHING, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 30, 1890.

Deaths reported 2,875; under five years of age 1,426: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 754, consumption 284, acute lung diseases 190, diarrhoeal diseases 514, typhoid fever 58, diphtheria and croup 58, whooping-cough 47, malarial fever 21, cerebro-spinal meningitis 16, scarlet fever 14, measles 12, puerperal fever 2, erysipelas 2.

From whooping-cough, New York 12, Chicago and Brooklyn 10 each, Baltimore 5, New Orleans 5, Worcester, Cambridge, Brockton, Salem, Haverhill and Taunton 1 each. From malarial fevers, New Orleans 9, New York 5, Brooklyn 3, Charleston 2, Nashville and Fall River 1 each. From cerebro-spinal meningitis, New York 5, Chicago, Brooklyn, Washington and Worcester 2 each, Baltimore, Lynn and Chelsea 1 each. From scarlet fever, New York 3, Chicago 4, Brooklyn 2, St. Louis and Boston 1 each. From measles, New York 9, Chicago, Brooklyn and

Baltimore 1 each. From puerperal fever, St. Louis and Cambridge 1 each. From erysipelas, New York and Baltimore 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending August 2d, the death-rate was 19.6. Deaths reported 3,649: acute diseases of the respiratory organs (London) 215, diarrhoea 343, measles 149, scarlet fever 77, whooping-cough 72, diphtheria 62, fever 35.

The death-rates ranged from 9.8 in Cardiff to 26.1 in Manchester, Birmingham 19.4, Bradford 17.8, Huddersfield 15.5, Hull 16.3, Leeds 16.2, Leicester 18.2, Liverpool 21.0, London 19.8, Newcastle-on-Tyne 23.5, Nottingham 13.6, Portsmouth 19.3, Sheffield 22.4, Sunderland 19.9.

In Edinburgh 15.4, Glasgow 22.0, Dublin 17.4.

The meteorological record for the week ending Aug. 16, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.*		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 16, 1890, TO AUGUST 22, 1890.

BRETIREMENT.

JOHN MOORE, Brigadier General, Surgeon General, August 16, 1890. (Act June 30, 1882.) Headquarters of the Army, A. G. O., Washington, August 18, 1890.

PROMOTIONS.

WILLIAM P. KENDALL, First Lieutenant and assistant surgeon U. S. Army, to be assistant surgeon with rank of captain, after five years' service, from August 12, 1890. Headquarters of the Army, A. G. O., Washington, August 18, 1890.

FRANCIS J. IVES, assistant surgeon, July 25, 1890. To be assistant surgeon with the rank of captain, after five years' service, in accordance with the Act of June 23, 1874. Headquarters of the Army, A. G. O., Washington, August 11, 1890.

With the approval of the Acting Secretary of War, leave of absence for four months, to take effect about September 1, 1890, is granted Captain WALTER REED, assistant surgeon, S. O. 192, Par. 17, A. G. O., Washington, D. C., August 18, 1890.

By direction of the Acting Secretary of War, a board of medical officers to consist of Major JOSEPH V. D. MIDDLETON, surgeon; Major CLARENCE EWEN, surgeon; Captain WILLIAM E. HOPKINS, assistant surgeon, will assemble at the U. S. Military Academy, West Point, New York, at 11 o'clock, A. M., August 27, 1890, or as soon thereafter as practicable, to examine into the physical qualifications of the candidates for admission to the academy. S. O. 192, Par. 1, Washington, D. C., A. G. O., August 18, 1890.

By direction of the Acting Secretary of War, First Lieutenant F. MASON, assistant surgeon, is relieved from further temporary duty at Fort Logan, Colorado, and will report for duty at his present station (Fort Washakie, Wyoming). S. O. 191, Par. 3, A. G. O., Washington, D. C., August 16, 1890.

By direction of the Acting Secretary of War, the replacement from active service this date by operation of law of Brigadier General JOHN MOORE, Surgeon General, U. S. Army, under the provisions of the Act of Congress approved June 30, 1882, is announced. General Moore will repair to his home, Bloomington, Indiana. S. O. 191, Par. 2, A. G. O., Washington, D. C., August 16, 1890.

The leave of absence for seven days granted Captain GEORGE MCCREARY, assistant surgeon, by orders No. 84, Fort Warren, Mass., August 13, 1890, is hereby extended fifteen days. S. O. 193, Headquarters, Division of the Atlantic, Governor's Island, New York City, August 15, 1890.

SOCIETY NOTICES.

THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS will hold its next annual meeting in the City of Philadelphia, Tuesday, Wednesday and Thursday, September 16, 17 and 18, 1890, in the hall of the College of Physicians, corner Thirteenth and Locust Streets. All physicians interested are invited to attend the several sessions.

WM. WARREN POTTER, *Secretary.*

E. E. MONTGOMERY, *President.*

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION will hold its Sixteenth Annual Session at Louisville, Ky., October 8th, 9th, 10th, 1890. An unusually interesting meeting is expected. An address is to be delivered by Dr. John A. Wyeth of New

York, and a paper to be read by Dr. Frank Woodbury of Philadelphia.

TRI-STATE MEDICAL ASSOCIATION OF ALABAMA, GEORGIA AND TENNESSEE. The next meeting will be held in Chattanooga, Tuesday, October 14, 1890, and will continue in session two or three days.

At our first meeting sections of the various departments of the medical sciences were created, with the following chairmen: Surgery, G. A. Baxter, Chattanooga; Gynecology, R. J. Tripp, Chattanooga; Obstetrics, W. T. Blackford, Grayson, Ga.; State Medicine, F. D. Sims, Chattanooga; Physiology, W. L. Gabahan, Chattanooga; Otology, R. D. Boyd, Chattanooga; Ophthalmology, N. C. Steele, Chattanooga; Laryngology, Max Thorner, Cincinnati, O.; Psychical Research, J. E. Furden, Cullman, Ala.; Pathology and Practical Microscopy, James E. Reeves, Chattanooga; Meteorology, E. T. Camp, Gadsden, Ala.; Practice, G. W. Drake, Chattanooga; *Materia Medica and New Remedies*, W. H. Jackson, Birmingham, Ala.

Members of the Association are requested to report cases or other matters of interest to the chairmen of the various sections, who will report them at the next meeting. The membership is not restricted to the three States, and all who can should join us in the furtherance of the above objects. By furnishing proper credentials and remitting one dollar to the Secretary any physician may be enrolled as a member of this Association.

OBITUARY. THOMAS T. GRIGGS, M.D., M.M.S.B.

Dr. Thomas T. Griggs, a respected and prominent citizen of Grafton, Mass., died August 12th, after an illness of about one year, of dysentery. He had been a resident of the town over fifty years, and for forty-one years practised as a physician, and was in the seventy-third year of his age. In his early days he attended the public schools of Sutton, and was employed as a clerk in a store. He went to reside in Grafton in March, 1839, where he graduated in medicine at the New England Medical College, Boston, and was granted a degree, M.D., July 18, 1849, from the Harvard Medical School. He at once began the practice of his profession with the late Dr. Pierce, and finally succeeded to his practice. He was a member of the Massachusetts Medical Society, and had served several years on the Board of Selectmen of Grafton, and was the senior Vice-President of the Grafton Savings Bank. In 1875 he was elected by the Republicans as Representative to the Legislature, serving as one of the Committee on Towns.

OBITUARY. JOHN ADAMS ALLEN, M.D.

Dr. John Adams Allen, of Chicago, dean of Rush Medical College, and for twenty-five years chief surgeon for the Chicago, Burlington and Quincy Railroad System, died August 15th after a lingering illness. He was born at Middlebury, Vt., on January 16, 1825. He graduated in medicine at Middlebury College in 1846. In 1859 removed to Chicago. Dr. Allen had travelled extensively. His journals, written during his travels in Europe and Africa, have had a large sale.

BOOKS AND PAMPHLETS RECEIVED.

De L'Anesthésie Locale Par Injection de Cocaine et Du Bon Effect De La Bande D'Esmarch. Par le Dr. E. Knauer, Chirurgien à l'Hôpital Butini, Privat-docent de chirurgie à l'Université de Genève. Genève: 1889.

Original Articles.

ERICHSEN'S DISEASE AS A FORM OF THE TRAUMATIC NEUROSES.¹

BY S. V. CLEVENGER, M.D., CHICAGO.

"WHAT'S in a name?" asks Shakespeare. Names, instead of being distinctive, are too often sources of confusion, as botanists, zoologists and anatomists are aware. Plants in the system of Linnaeus were specifically named "montana," when they were not exclusively mountainous; animals called "fluvitiale" were later found often in lakes; the "pituitary gland" is neither pituitary, nor a gland; the arteries were named as air receptacles; and so we might multiply misnomers indefinitely because of the attempts of our ancestors to make names superficially descriptive.

About twenty-five years ago Erichsen described a variety of derangements following upon concussion of the spine. Now nothing could be simpler, apparently, than the expression "spinal concussion," and nearly every one fancies that no misunderstanding could arise in the use of such a term. Nevertheless, that very title has in itself occasioned great misunderstanding, because it had a restricted as well as a general meaning.

The cause of this confusion dates from Erichsen's description of the different kinds of ailments that may arise from blows to the back, such as severe direct injury to the spine, causing demonstrable cord lesions, slight indirect or remotely occasioned back injuries, sprains, strains, wrenches and twists of the spine, wherein occurred cord compression by extravasation or inflammatory exudations, nutritive cord alterations, and a "functional disorder" caused by a spinal concussion. In the interests of scientific medicine I named that so-called functional disorder "Erichsen's disease," because John Eric Erichsen was the first to describe this particular group of symptoms that often followed upon concussions.

That distinguished London surgeon wrote to me as follows:

"I assure you that I feel much gratified and very highly flattered by having my name appended by you to the group of symptoms so very characteristic and remarkable, when taken in the concrete, which I believe that I was the first to describe, which result from that peculiar form of spinal injury now recognized under the term 'spinal concussion.'"

Had Erichsen given any sort of a name to this disorder, however arbitrary that name might have been, there would have been less occasion for the wrangling that has occurred in court-rooms all these years.

Instead of entangling ourselves in the endeavor to explain that spinal-concussion symptoms may sometimes be induced by a spinal concussion, misunderstanding is impossible when we state that a concussion of the spine may originate a vast range of troubles, such as dislocation of the vertebrae, cord injuries, etc., and it may also cause Erichsen's disease.

What, then, is Erichsen's disease?

It is a serious disturbance of the functions of the spinal cord, without there being demonstrable cord lesions. Such disturbance can be best accounted for by supposing that the spinal sympathetic system has been deranged, secondarily interfering with the blood-

supply of the cord and its membranes, conjoined with other vaso-motor phenomena, such as emotionalism, flushings, cardiac rapidity, hyperhidrosis, sleeplessness, headaches; directly due to the original sympathetic system derangement.

The fact that the group of subjective symptoms and objective signs are distinct from other disorders, sufficiently set it apart from other ailments or "traumatic neuroses," and justify its special title. The claim is sometimes made that naming diseases after individuals is unscientific, and burdens our nomenclature unjustifiably. This is true only in a certain sense, and it is easy enough to formulate a law when such christening would be proper.

The golden mean can be observed in this as in other respects, and the matter is one of such great importance that I do not hesitate to take up time in its elucidation. No trivial reason should justify such naming, but when there is an eminently proper cause for so doing, such as in this instance, the medical world profits by having the discoverer's name forever associated with the disorder.

If a disease can be accurately named descriptively, then the descriptive name should be preferred; but the risk is run that, with the advance of knowledge, the name ceases to be descriptive, and too often absolutely erroneous and misleading. At one time the scutum was dubbed sacred, as the seat of the soul, because supposed to be imperishable. A formidable disease became universally prevalent after the return of Columbus from America, and we were threatened with its perpetuation as the "American disease," just as, at one time, its companion was known as *Französische Krankheit*; but as attention was called to the fact that the greatest pretenders to piety were the most numerous sufferers, a diversion was made in favor of the title "holy sickness." The etymology of the word syphilis is obscure; and hence the name is arbitrary, and becomes as much of a *nomen proprium* as had it been called "Smith's disease" or "Jones's disease." Gonorrhœa is a misnomer, because it means a flow of sperm.

Huxley opposes descriptive names, in the main, in zoölogy, and holds that we should forget the etymology of any animal name, and use it merely as a title, without regard to its origin.

Descriptive naming is carried to extremes by savages, in such appellations as "Sitting Bull," "Red Jacket," "Man-afraid-of-his-Horses"; and the tough element in our cities describe one another as "Shorty," "The Bruiser," etc. I merely mention this as an offset to the radical claim that diseases should in no case be named after those who first described them. Purely arbitrary names, that convey no descriptive meaning, often have decided advantages, the foremost advantage being that an arbitrary name, such as "Bright's disease," "Addison's disease," "Graves's disease," cannot possibly mislead. You receive the history of the disorder in the name, and are compelled to learn what it was that Bright, Addison and Grave discovered.

I was disposed to the belief that this sort of thing could be overdone, through naming of such complaints as "Thomson's disease," disorders such as the "Cheyne's-Stokes' breathing," "Argyll-Robertson pupil," but as the law of survival of the fittest would overtake inappropriateness in this regard, I now incline to thus honor discoverers; and we all realize

¹ Read before the Jurisprudence Section of the American Medical Association, Nashville, Tenn., May 22, 1890.

that little enough honor is earned by any delver in our profession, however conscientious and gifted.

Let me tell you of an instance where immense advantage would have been gained by avoidance of attempts to describe a disease in a name. The terrible form of insanity now called "paretic dementia" by alienists, was first described by Bayle in 1822-26. Later, Calmeil missed the opportunity of his life, because, while he clearly recognized the differences it presented from other forms of insanity, he did not attach his predecessor's name to the malady, as he should have done. So doing, would have saved thousands of insane from the gallows, the guillotine, and the prison. Could we have had "Bayle's disease," instead of the present abominable array of misnomers, every physician would have known something about it, and recognized it as an entity, instead of to-day having to learn that there is a disorder that suddenly attacks some overwrought business men — often the rich than the poor, the ambitious rather than the drone, the intellectual rather than the thoughtless; the trouble that killed Sir Walter Scott and other historical personages — a trouble whose pathology has been worked out even better than has been that of pneumonia; a mental ailment that presents distressing problems, mainly because so few know what is absolutely known concerning it. It is too late to call it "Bayle's disease." It is with the utmost difficulty that the recent designation "petic dementia" is favored. I speak to you of the affection that has been called in our books "general paralysis of the insane," "progressive general paralysis," "general paroxysm," "general paresis," "paralytic dementia," "progressive paresis," or "dementia paralytica," and their equivalents in French and German. Not one of these descriptive names really described the disorder; and excellently-educated physicians, not versed in this particular matter, have been led into deriding the very existence of the complaint, through taking the name as descriptive. Fordyce Barker, of New York, who was a specialist in everything, aroused the applause of the court-room mob in the Guiteau trial by swearing that there was no such thing as "general paralysis," except in death. Yet doubtless not one in that court-room but would have thought he understood precisely what was meant had the atrociously lying name, "softening of the brain," been used instead.

A volume could be written upon the accursed influence of that word-grouping, "softening of the brain." It has been used in a metaphorical sense for a century — in the ignorant mind, satisfactorily descriptive of what to the pathologist is complex, and oftener involves sclerosis, atrophy, or putting it popularly, "hardening of the brain."

While pathologist of the Chicago County Asylum, the certificates I filed from the thousand city practitioners included in "softening of the brain," at least, fifty dissimilar insanities, such as melancholia, paranoia, atherosomatous insanity, hebephrenia, mania, kata-tonia, circular insanity, confusional, stuporous insanity, and even terminal dementia. Every insanity almost was "softening of the brain."

Every physician in the world should remember that from the standpoint of the alienist there is no such disease as "softening of the brain." The pathologist can tell you of various kinds of brain softening: red, yellow and white, that are merely degenerative processes, more often associated with paralytic than men-

tal phenomena, subsequent to extravasation, embolisms, thrombosis. Whosoever speaks of "softening of the brain" as a mental derangement, either caters to ignorance, or is himself ignorant of alienistic science.

Turning again to scientific nomenclature, we find precision in electrical science in the meaning of naming of measurements — farads, watts, ampères, ohms; and in currents — the faradic, galvanic, and franklinic after Faraday, Watts, Ampère, Ohm, and Franklin. Very true, the names themselves convey no meaning to the un instructed in electrical science, just as the term "Erichsen's disease" would compel some attention as to what was meant, though every ass would suppose he knew what was included in "concession of the spine" and "softening of the brain."

Oppenheim, of the Berlin University, carefully studied the effects of concussion accidents, and, incidentally, some nerve injuries, and included all under the title "traumatic neuroses"; and forthwith, that name has been adopted by several writers in lieu of "spinal concussion." The impropriety of this is evident when we reflect that, while Erichsen's disease may be a traumatic neurosis, sciatica, paralysis agitans, chorea, myelitis, epilepsy, and myriad diseases, may also be traumatic neuroses; so that term is too generic; and the fact that Erichsen's disease is of medicolegal importance does not warrant so sweeping a designation for it in which can be included thousands of other ailments.

S. Weir Mitchell, during the late war, made extensive researches with regard to direct injuries to nerves; and the traumatic neuroses described in his book differs widely from those investigated by Oppenheim.

Sterling and Krontal, in the *Neurologisches Centralblatt*, June 1-15, 1889, report a case that died from cardiac and pulmonary disease. The autopsy revealed arterial sclerosis to a marked degree, with occasional hyaline and fatty degenerative spots in the entire arterial system, particularly in the cerebro-spi-nal vessels. The trunk of the sympathetic was peculiarly degenerated. There were scattered degenerative spots in the white part of the cord, and in the gray of the lower dorsal region, and a small hemorrhage in the mid-dorsal region. This sympathetic and arterial degeneration lends great plausibility to the theory I advanced, that the spinal-sympathetic was the main seat of the disorder.

Meynert, in the *Wiener Klin. Woch.*, 24, 26, 1889, locates the seat of the "traumatic neuroses" in the forebrain. Now, no one can have a greater regard for the opinion of this famous cerebrologist; but occasionally, Meynert can be as wrong as Charcot or Pasteur. Much of this fallibility comes from the impossibility of a single mind, however trained, grasping all aspects of the limitless field of human knowledge. In these days it is the ignorant alone who claim to be thoroughly instructed in all departments of medicine and surgery.

The depths of our attainments are inversely as their breadth; and the specialist is narrow whose career was not begun as a general practitioner. To be a pathologist and nothing else, a neurologist and nothing else, may confer ability in some few particulars; but breadth of thought can only be brought to bear upon a special line through previous cultivation in many fields.

Meynert has studied the minute anatomy of the brain, but he has not studied spinal concussion in all

its aspects; and his immense knowledge of the cerebrum is misapplied in endeavoring to locate the vast range of general vaso-motor phenomena in a single lesion of a restricted part of the brain.

DISCUSSION.

DR. HERBERT JUDD, of Galesburg, Ill., began the discussion in a paper entitled "Legal Aspects of Spinal Concussion":

In connection with the discussion of the legal aspects of spinal concussion, I beg to say that, during the past twenty years, I have known of twenty-six cases, all in the State of Illinois, of so-called concussion of the spine that have been brought to my notice, and which I have watched with some interest while the cases were under consideration by attorneys for corporations against which claims for damages had been preferred. I have known of many other cases of this disorder in which there existed grave doubts of the patient having sustained any injury, but the twenty-six cases referred to can be verified by the files of papers in the office of the attorney of the Chicago, Burlington & Quincy Railroad Company at Galesburg, Ill., and the affidavits and evidence there preserved. When the liability of the railroad company for whatever damages the claimant had sustained was conceded, there were but few of the cases litigated, but were settled prior to suit in some cases and prior to trial in others. In all the cases I specially allude to, the genuineness of the claim, that of permanent injury from shock or concussion of the spinal cord, was denied by the railroad attorney, upon the candid opinions of surgeons and physicians obtained by the company. In every case, however, the railroad attorney negotiated the best settlement possible, and usually regarded it as good policy to pay liberal sums rather than submit to a trial, when courts could not give protection against perjured, prejudiced, and ignorant testimony.

Some of the cases had "litigation symptoms" for a long time prior to settlement. Several of them were so serious as to render the patient bedridden and helpless, but in all of them thorough and complete recovery resulted. In most of them recovery was rapid and rather astounding, and it was noted that improvement followed swiftly after the "damages" were paid.

Understand, that in all these cases the only question in controversy was that of actual injury. They were cases in which the symptoms were subjective, and the condition of the patient could be determined alone upon his statement, to which too much credence is often given by physicians. These were cases where it was deemed the best financial policy to submit to blackmail to avoid legalized robbery, the amount of which depended upon the sympathies of a jury with a claimant, and their unreasonable prejudices against corporations, all of which they assume to believe are immensely wealthy, and able to stand the assessment. I know of no case of actual, patent injury caused under such circumstances as to create a legal liability, where there was any serious trouble in arriving at a fair and just sum to be paid as damages, satisfactory to both parties; nor do I ever expect to see a case of actual, permanent injury in court and on trial where the question of liability has been conceded. All such honest, just claims can be and ordinarily are settled out of court. I have little faith in book cases of spinal concussion.

These special cases I have referred to had their origin in the hints, suggestions, and help of Erichsen. The study of Erichsen began with date of accident to train, — the patients were crammed with directions for fraud. The cases I have in mind were carefully watched and traced up after settlements were made. This was done as a source of information, and to verify, if possible, the views of fraud entertained; and, as I have already stated, every one of them recovered, and in several of them the fraud became so apparent as to cause some notoriety to the patient, and some unenviable notoriety to the advising physician, especially in a few cases of complete recovery after a long and no doubt laborious siege of "total disability."

I believe there is a maxim of the criminal law, that every person is to be regarded as innocent of crime till proved to be guilty. It seems about time that surgery should have and act upon this maxim, that every person claiming disability from concussion of the spinal cord, where no objective symptoms are to be discovered, is to be considered as planning for your aid in enabling him to rob some employer, until you can, by your own knowledge of the case, discover that injury actually exists.

If physicians would or could consider and treat all cases of alleged spinal concussion without regard to or any consideration of the desires of the patient to reap a money compensation, there would be less difficulty in effecting cures. If the physician would confine his services strictly to his own duty to effect a cure, and refuse to consider or meddle with the financial or pecuniary plans of his patient, he would attain much more brilliant success in his treatment. If he in good faith endeavors to effect a cure and not to establish a case of permanent injury for the pecuniary benefit of the patient, or to gratify his avarice, he would find few cases of the disease under consideration.

How many cases of concussion of the spinal cord can any of you recall in your own practice, where the patient fell from a load of hay, or was thrown from his own wagon, or fell from a barn-loft, or received injuries or met with an accident for which no one but himself or his own family was blamable? If you would consider these cases as you consider and treat spasms in children during the first and second dentition, or fits resulting from worms, you might be led to better means of improving the physical condition of the patient. If you refuse to minister for the benefit of the patient's estate, and apply your skill to his person, you might acquire more success. If you exert your proper influence to keep your patient out of the hands of the "calamity lawyer," and to shut out from his mind all present consideration of the possible pecuniary gain, you would have taken a giant step toward his cure. Is it not our duty as physicians to benefit the physical man, even at the expense of property? Is not health worth more than riches, even honestly gained?

I have said this much with the sincere desire for the best good of the profession. Facts are "brutal things to deal with."

DR. CLARKE GAPEN, of Omaha, Neb., agreed with Dr. Clevenger, that the disease described by Erichsen under the name "spinal concussion" should be renamed "Erichsen's disease," not only to fix it more accurately, but because a large amount of obloquy attends the subject which Erichsen ought to bear. This book is said to have cost English railways fifty million dollars,

and American railways as much more. Dr. Gopen had taken Erichsen's cases and classified the symptoms under objective and subjective heads, and was amazed to find how few were the objective. His experience in the main had agreed with that of Dr. Judd, in that most of the cases were either hysterical or malingerer. Moreover, many of the symptoms, as flushings, increased temperature, emotionalism, were in fact cerebral symptoms rather than spinal. There were no vaso-motor centres in the spinal cord. Page has shown how very difficult it is to injure the cord, owing to its looseness in the bony canal and the fact that it is surrounded by fluid. Actual injury is very rare, and usually well-marked from the outset.

DR. H. N. MOYER, of Chicago, stated that he was astonished at Dr. Judd's statement that concussion cases did not occur unassociated with damage suits. Dr. Judd's experience must be limited, indeed, to allow him to make a remark of that kind; for in the past five years Dr. Moyer had seen a large number of concussion cases in which there was no suspicion of a damage suit; and these did not differ at all in course, symptoms, duration or termination from those that had been the subject of legal contention. Dr. Moyer heartily agreed with Dr. Clevenger in suggesting the propriety of the term "Erichsen's disease." While it is not all that one could desire, yet it is such an improvement upon "spinal concussion" that it should be adopted, at least until the pathology and the morbid anatomy of the condition shall be better understood.

DR. O. EVERETT, of Cincinnati, said: I approve the suggestions of the paper, and think that the adoption of the term "Erichsen's disease" would be proper and useful. If a definite term is used by a medical man, such as "Bright's disease" or "Basset's disease," or for surgical operations such as "Battley's," it is usually or presumably because he has definite ideas respecting conditions thus named after original investigators, while general terms, such as "spinal concussion," "kidney disease," etc., do not convey such definite ideas, or other than vague notions of some disorder. It is convenient, however, for practitioners who are not scientific, to have these general terms for use in emergencies. They sound well, and if delivered with proper expression, go a great way in confirmation of one's reputation for wisdom. For example, the term "softening of the brain." If one meets with serious cerebral symptoms, all that is necessary to say with becoming gravity and a significant look, "Softening"; and the whole business is settled. "Congestion" used to be the favorite term by which to account for failure in treatment of various forms of disease terminated often unexpectedly by death. All the baffled practitioner had to do was to shake his head and say, "Congestion." Such terms are convenient for the concealment of ignorance. The name of Erichsen is worthy of commemoration, and may well be associated with a form of disease which he has so well described.

DR. J. G. KIERNAN, of Chicago, stated that he had the clinical experience of Dr. Moyer. That railroads were not always of the type described by Dr. Judd was shown by the Chicago railroad "jury fixing" cases. That spinal concussion existed, the case reported by Dr. McIlvaine of Peoria would alone demonstrate. A female victim of a railroad accident had been suspected by Dr. McIlvaine of being a malingeringer. She had secured damages, but the spinal disease had gradu-

ally progressed into helplessness and death. Dr. Kiernan had himself seen similar cases.

DR. G. FRANK LYDSTON said: I consider the work which Dr. Clevenger has been doing upon the subject of "spinal concussion" a most important advance in medicine. His adoption of the term "Erichsen's disease," while open to some objections, is, on the whole, a wise and useful plan. The laity have already learned that "spinal concussion" is an omnibus which may be made to cover much malingering. By the adoption of "Erichsen's disease" we will at least compel the humbug to learn his lesson over again. The term will certainly convey to the malingerer the idea of a distinct and definite affection, which he must substantiate by plain and positive proofs. I am aware that it is not easy to evolve order out of the chaos of symptoms which characterize the results of concussion of the spine, but as far as may be, I believe that Clevenger has accomplished it. His explanation of the pathology of the varying phenomena is thus far the only rational and intelligible one in medical literature. I regret that he has not said more of his theory to-day. Personally, I would advise those who are not familiar with his views to read his book. If others derive the same benefit from its perusal that I have done, they will feel amply repaid.

In closing the discussion DR. CLEVENGER stated that he had been astonished at the improvement of some patients after the settlement of damage claims, but this seemed to be due to the relief from worry which the conclusion of the suit afforded; but it would be presumption to affirm that such cases were entirely cured until years had elapsed and unprejudiced opinion had been engaged. This "quick cure by settlement" savored too much of the unscientific assertions of Herbert Page, who was the most ordinary special pleader for railways, while both Dr. Gopen and Dr. Judd had been opposed to Dr. Clevenger in recent suits against corporations, and seemed to look at the matter from one standpoint, the latter had frequently been called as an expert for either side, and sometimes for both sides at the same time.

The statement that there were no vaso-motor centres in the spinal cord, and hence the symptoms were cerebral, was rather surprising when the sympathetic system is so intimately united to the spinal all the way down the cord length; and such ordinary matters as constipation and hemorrhoids producing brain troubles show that such a vaso-motor difficulty as emotionalism need not have its origin, necessarily, in the head.

The intimation that subjective symptoms were always false when made the bases of claims against railways, is on its face absurd. Physicians have to judge from their consistency, whether they are real or not. Contrary to Dr. Gopen's findings, Dr. Clevenger had devoted all his spare time for three months in analyzing Erichsen's cases, and found an abundance of objective signs in all. But it depends upon what is meant by "objective." To the uneducated the galvanometer and electrical indications convey no meaning. Paralysis and insanity of the gravest kinds would present nothing "objective" to the biased witness.

There are cases in which no honest opinion can be reached, and in such it is best to allow the mind to remain a "scientific blank," as Huxley advises. Only the untrained imagine they must have a positive opin-

ion upon everything under the sun. Sometimes a little waiting will determine matters. A case examined a year ago presented nothing but purely subjective symptoms, and to-day there is atrophy of an arm. In another instance, a laborer fell partly into a coal hole, with one leg in and the other out, and after a year is unable to do any work, but there was such an utter absence of anything in the way of electrical or other findings, and so many of the ordinary symptoms of Erichsen's disease were missing, that Dr. Clevenger told the lawyers that everything depended upon the credibility of the patient, and he preferred having nothing to do with the case as it stood at present.

We find instances, in and out of the books, of fatal issues among patients accused of malingering. We occasionally find a conscientious railway surgeon who acknowledges that railway accidents do not always improve health, and that a few dollars' settlement will not resurrect the dead.

A CASE OF GASTROSTOMY.

BY GEORGE W. GAY, M.D.,
Visiting Surgeon to the Boston City Hospital.

EARLY in the summer of 1889, Mr. W., a large-framed, powerfully built man, about fifty years of age, came to my office, complaining of inability to swallow anything but liquids. This difficulty had been gradually increasing for about a year. He had lost much flesh and strength, and was slowly starving to death. Hungry all the time; felt that he could eat anything, and in large quantities if he dared to do so. He was obliged to confine himself to liquids, and could take those only in small sips, otherwise they were immediately regurgitated. The first mouthful, as he said, was all right, but after that "everything comes up." There was no sharp pain, merely a sense of pressure. Had lost thirty pounds in weight during his illness, and was in a pitiable condition.

On exploration with the esophageal bougie, only the next to the smallest size could be passed through the stricture, which was located behind the sternal notch. Glands in the neck were somewhat enlarged. Nutritive enemas of milk and beef juice were ordered every six hours. These afforded only partial relief, and the man begged to have something radical done. He was anxious to take any risk for relief, and under the circumstances I finally consented to accede to his urgent solicitations to open the stomach, in other words, to do gastrostomy.

The operation was done at the City Hospital, under ether, on July 21, 1889. An incision four inches long was made, an inch and a half below the border of the ribs on the left side, commencing about two inches to the left of the ensiform cartilage. On dividing the peritoneum to the extent of an inch and a half, the stomach was found collapsed about five inches from the anterior abdominal parieties. It was drawn into the wound, and placed under easy control by means of two wire loops about three-fourths of an inch apart, passing through the outer coats of the stomach. The organ was then secured to the edges of the wound by means of silk sutures, the peritoneal surfaces being carefully apposed all around the abdominal incision. Finally, with a tenotomy knife an incision, or rather, a puncture, was made into the stomach not over a quarter of an inch in size; just large enough, in fact, to

admit the point of a small glass tube, which served as the nozzle to the syringe or feeding apparatus. Eight ounces of warm peptonized milk were slowly injected into the stomach, and the small opening securely closed by simply twisting the wire loops very loosely. The dressing consisted of iodoform gauze and swathes.

The patient rallied well from the anesthetic. He was fed every five hours in the following manner: Half a pint of warm peptonized milk, with or without bovine, was slowly poured into a small glass funnel, to which was attached a rubber tube about two feet in length, this being about the fall required for the liquid to flow easily into the stomach. The patient declared positively and repeatedly that he felt much less hungry, and less prostration and restlessness after the artificial feeding was commenced. He even felt so well that he got out of bed, although warned against doing so. He lay in bed, received his food regularly, and was comparatively comfortable, requiring no morphia till eight days after the operation, when he was seized with severe pain in the epigastrium, due probably to separation of adhesions about the wound. The distress was readily controlled with morphia, given under the skin. Two days later he had a sudden and severe attack of dyspnoea, amounting, in fact, to orthopnoea. It did not persist, and gave little trouble afterwards.

Fifteen days after the operation some difficulty was met with in trying to introduce the tube into the fistula, and the liquid caused pain, indicating that, in all probability, it did not enter the stomach directly, if at all, but rather some adventitious cavity outside that viscous, a fact proved by the autopsy. Rectal feeding was substituted for three days, when the method by the artificial operating was again resumed. At this time the stomach began to get irritable, and the food was rejected soon after being introduced. The strength began to give way; a moderate febrile condition developed; consciousness was retained to the last; food was rejected both from the stomach and from the rectum. He died from exhaustion twenty-six days after the operation.

The post mortem diagnosis was as follows: chronic pulmonary tuberculosis; cancer of the esophagus; acute diffuse peritonitis; senile atrophy of the kidneys; chronic pleurisy; cloudy swelling of kidneys and liver.

Three small, ragged tuberculous cavities were found at the apex of the right lung. It should have been stated above that a troublesome cough developed during the last few weeks of the patient's life. It was never severe enough to call for special treatment. At the autopsy it was found that the external wound communicated with the stomach, and also that a cavity had formed between the stomach and spleen and surrounding tissues. A certain amount of the food had evidently entered this cavity, thereby causing the pain. About half a pint of whitish opaque fluid was found in the peritoneal cavity. The peritoneum in the region of the liver was lined with an opaque white membrane. The surface of the stomach was of a diffuse red color, on the posterior and lower portion, the rest of the walls being dark green from post mortem changes. Glands somewhat enlarged.

The whole circumference of the esophagus for two inches above the sternal notch was the seat of a rough, elevated, nodular growth, having an irregular outline, and being fully an inch thick in one place. It was more especially developed on the posterior surface

of the canal. The microscope showed the growth to be composed of "reticulated connective tissue, with epithelial cells in spaces."

Did this man get sufficient relief to encourage us in repeating the operation under similar circumstances? I have no hesitation in saying that he did. It is fair to conclude that he lived as long and had less suffering by reason of the operation. The only alternative was hypodermic morphia, a rather poor substitute for food. The breaking down of adhesions between the stomach and parietes was probably unavoidable, on account of the great antero-posterior diameter of the abdominal cavity. If a patient with nearly complete occlusion of the oesophagus is so weak that he evidently has but a short time to live, it is doubtful if much benefit is to be derived from this operation. But, under opposite circumstances, if the person is able to be up and about, and has prospect of some weeks or months of life, a very considerable relief to the gnawings of hunger, and its attendant restlessness, may be confidently expected from the procedure. Under these circumstances the operation is to be recommended, provided rectal feeding fails to accomplish the object.

HEART-FAILURE.¹

BY E. N. WHITTIER, M.D.,

Visiting Physician, Massachusetts General Hospital.

THE opinion, which prevails among the laity as well as in the profession, that during the winter of 1889-90, there has been a large increase in the number of deaths from "heart-failure," is certainly well grounded, for at no previous corresponding period in the experience of this generation have so many instances been observed and recorded, of inability on the part of the heart to perform its functions.

[From the statistics of the Boston Board of Health, courtesy of Dr. Durgin, chairman.]

I offer this paper in examination of the contributing as well as of the underlying causes inducing the opinion thus formed.

The factors which combine and find expression in the opinion so widespread and so prevailing are

(1) An epidemic of large proportions, having special influence in the direction of cardiac exhaustion: primarily because the disease itself is essentially a disorder of the nervous apparatus, in which cardiac and thermo-toxic centres are extensively involved; secondarily, in that it has as a predominating complication, broncho-pneumonia.

(2) A season of the year in which pneumonia, as primary diseases, have always occupied prominent positions in the mortuary statistics, and all recognize the immediate and positive relation of acute pulmonary inflammation to cardiac failure.

(3) A higher and constantly increasing knowledge of the important position occupied by the myocardial disorders in the pathology of heart disease, and their high rank among the diseases which contribute to the death-rate; for it need not now be said, as Rénoy justly observed in 1883, "that the brilliant achievements in the diagnosis of valvular disease effected by means of auscultation, have led to some injurious neglect of the non-valvular diseases of the heart."

We are all familiar with the classical divisions, fatty degeneration, fatty infiltration and fibroid disease of the heart, but of late, changes in nomenclature have brought prominent to the front in the later writings, the terms arterio, capillary, fibrosis, defining peripheral changes; arterio sclerosis, defining changes in the larger arterial trunks, and myocardial sclerosis or arterial sclerosis of the heart expressive of the changes which take place in the muscular structure of the heart or in the inter-ventricular septum, a most important point to be borne in mind. I do not propose to discuss at any length the older and better known divisions, but rather to present some of the later views on the subject of the vascular changes which sustain a causal relation to sudden death.

Dr. McWilliam, in his admirable article on heart-failure, in the *British Medical Journal*, January, 1889, cites Ludwig, Hoffa and Kronecker, and presents a synopsis of their careful studies on the subject under consideration. I may further state that I do not deem it profitable to discuss on this occasion, as of primary importance, the influence on the duration of life of the gross lesions, wherein the physical signs are fairly well marked, but the more important of the causes of sudden death from cardiac failure wherein no large and appreciable lesion exists, ante-mortem.

Formerly, it was assumed that cardiac failure took place with greatest frequency in the midst of quiescent standstill in a state of diastole, but it is now just beginning to be considered more probable that sudden arrest

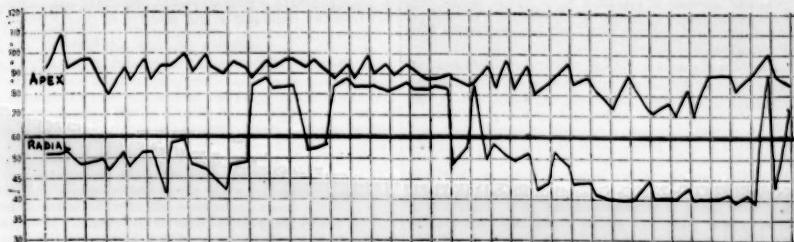

Chart illustrating the difference between the Pulse at the Radial and the Apex in cases of Heart-Failure.

of cardiac function does not usually take place during diastolic pause, but that, on the contrary, there is set up a violent though irregular inco-ordinated manifestation of ventricular energy; that is, in the majority of cases of sudden death from this cause the ventricle is overloaded, not because its muscular walls are at rest, but because there is tumultuous activity, irregular in character and wholly ineffectual as regards its results, because of the inco-ordinate action of the cardiac muscular bundles, whose normal function is co-ordination, regularity and effective propulsion of ventricular contents, or in other words, an incomplete and ineffectual ventricular systole. To this most important division of the subject I consider we must look for the best explanation of the *immediate cause* of sudden death in "heart-failure."

We note an apparent discrepancy in the reports of autopsies following sudden death in "heart disease;" in some, large and quickly detected evidences of disease are mentioned, in others, lesions relatively insignificant in gross appearances and in extent are found to have been productive of one and the same result.

McWilliam claims that this may be explained by the existence in the heart, as in the brain, of regions tolerant or indifferent in regard to destructive lesions, and of other intolerant regions; and one of the regions most intolerant of myocardial changes, and most productive of the results forming the subject of this paper, is the inter-ventricular septum.

One of the most competent observers estimates that in about ninety-five per cent. of cases of sudden death from "heart failure," as shown by autopsies, the heart itself was disorganized. Chronic myocarditis existing as a degenerative process, in connection with chronic inflammation affecting the cardio-vascular system as a whole, and notably the coronary arteries.

Balfour's articles in the Edinboro *Medical Journal* of last year on the senile heart, present carefully considered conclusions well worthy of consideration.

He places much stress on the causes which lead to dilatation and are associated with impaired nutrition of the myocardium, and diminish its power of overcoming the resistance established in the arterial walls through the influences of advancing age. Balfour discusses at considerable length the subject of sclerosis of the coronary arteries, as a most important factor in that impairment of power, "heart-weakness," so evident when heart-failure declares itself in the presence of violent emotions, sudden over-exertion, and in the onset or during the progress of obstructive inflammatory disorders, notably of the pulmonary tissues.

Recent studies and observations of the conditions found associated with chronic endarteritis have also thrown much light on the causes of heart-failure, a result of disease of the walls of the heart from retrograde changes in the vascular system, extra-cardiac, principally, if not wholly, arterio-sclerosis or loss of arterial elasticity, whose chief objective signs are an accentuated second sound in the aortic area, a firm, tense pulse, and a pulse-tracing, indicative of high arterial resistance, or as is frequently expressed a pulse of high tension.

Balfour adds as an important contributing element in heart-failure, the conditions of the peri-vascular tissues, the vascular environment, flooded as it always is with blood plasma, establishing an inter-arterial pressure, a more important source of peripheral resistance than is found even in the sclerosed peripheral arterial walls.

Allbutt, Roy and Adams, Stokes, Gairdner and Bristowe, and a host of other observers, may be cited in further confirmation of the views now entertained bearing on the influences on heart of increased peripheral resistance.

Huchard and Weber have studied with great care the subject of arterio-sclerosis, primarily, peripheral, secondarily, proximate, and finally, myocardial, as induced by an intoxication, by a diathesis, or by excesses, all of which tend to increase resistance in the arterial walls.

These observers describe the local myocardial effects under three heads: dystrophic, in which the sclerosis is first established in each vascular territory as far as possible from the corresponding nutrient artery, so that the muscular substance deteriorates centripetally; whereas in the second variety, inflammatory, the inflammation is primarily a peri-arteritis, and by centrifugal extension is propagated to the myocardium; in the third variety there is a mixed condition, an endo-peri-arteritis.

Clinically the picture is less distinct, the symptomatology is so defective that a differential diagnosis cannot be established during life; for myocardial-sclerosis is only one of the local results of a disseminated arterial sclerosis, found simultaneously in other important organs beside the heart.

I have the privilege of presenting here extracts from advance sheets of an article on Diseases of the Heart and Pericardium about to be published in Sajous's American Annual, in the preparation of which I have the great pleasure of acknowledging the valuable services of Dr. Vickery and Dr. E. M. Greene.

Cardiac sclerosis is preceded by a latent period, the symptoms of which, according to Huchard and Weber, are a firm, small pulse, with a sudden rise and rapid fall; a state of arterial tension exaggerated in consequence of an intermittent or permanent spasm of the peripheral arteries, which often causes pallor of the face and integuments, local anemia, and sensation of coldness wrongly attributed to the condition of the kidneys; polyuria, palpitation at night or during digestion, disturbed cardiac rhythm, and tachycardia; rapid pulse, pulsation of arteries, physical and intellectual fatigue, cerebral sensations of lightheadedness and vertigo, strong cardiac pulsation over an increased area, signs of cardiac hypertrophy. Huchard has pointed out the frequency of permanent or temporary smallness of the left radial pulse, and insists on the importance of the accentuated second aortic sound. At length, the cardiac lesion plainly manifests itself. The phenomena are not always the same, but several symptomatic forms may be distinguished. Huchard distinguishes five types symptomatically of arterio-cardiac disease: (1) *Pulmonary*, often marked by violent attacks of cardiac asthma, feeling of oppression in chest, and weight in epigastrium, dyspnea without albuminuria. (2) *Painful* type, simulating angina pectoris. (3) *Arythmic* type, with two subdivisions: (a) cases marked by sudden violent disturbance, called *folie du coeur* (insanity of the heart); (b) a permanent but insidious arrhythmia without symptoms, often discovered by accident. (4) *Tachycardiac* type, transitory or permanent, pulse ranging from 150 to 220 beats a minute. (5) *Aystolic* type, the most important, a result of acute dilatation of the left ventricle.

Huchard recognizes three successive stages of the arterio-cardiac sclerosis: (a) pre-arterial, increased arterial tension without vascular lesion; (b) cardio-arterial, vascular endarteritis, at first peripheral, then visceral and myocardial, always associated with increased arterial tension; (c) mitro-arterial, dilatation of cardiac cavities, auriculo-ventricular orifices, and, above all, lowering of arterial tension.

The aystolic condition of valvular origin is slowly and progressively developed, and its course measured by gradual peripheral edema, visceral congestions, diminished amount of urine, and all the signs of cardiac weakness; on the other hand, arterio-cardiac aystole is marked by a sudden, unexpected, acute onset. A sudden spasm of the vessels causes increased resistance, and demands of the degenerated heart a corresponding muscular force which it does not possess. Slight fatigue, simple bronchitis, or some scarcely appreciable cause precipitates a condition of frightful dyspnea, cyanosis, and feeble pulse. These attacks may be repeated at intervals of several hours or several months. They finally bring on edema, diminished urine, albuminuria, permanent aystole—a condition which is easily mistaken for that form of valvular disease in which the souffle is not heard, owing to the weakness of the cardiac contractions.

Prognosis depends on the type and intensity of the symptoms and the complications. The chief therapeutic guide is the condition of arterial tension. For increased tension, iodides, nitrates, blood-letting. Digitalis is contraindicated. In lowered tension, digitalis.

Huchard² describes the aystole or, better, cardiotactic form of arterio-sclerosis of the heart. This is the most important variety of arterio-sclerosis, and has the gravest prognosis. The sudden, unexpected, frequent attacks of aystole which supervene in the course of cardio-arterial disease present distinct courses which are not met with, to the same extent and in the same form, in cases of simple valvular disease. In the latter we can almost foresee the course of the disease, and the myocardial insufficiency, progressively increasing, is measured by peripheral edema and repeated congestions, which invade, in turn, the viscera and tissues, by scarcity of urine, diminished praecordial shock, and all the signs of cardiac weakness. In cardiac disease of vascular origin, on the contrary, the most marked aystole appears suddenly. It may, as in valvular affections,

be accompanied by edema, anasarca, or passive hyperemia. But from the beginning it may also run its course without edema or congestions. It is asystole in the true sense, because the heart alone appears affected and undergoes acute dilatation, for which the insidious and latent lesions of the cardiac muscle have long prepared the way. In the first case, vascular weakness and progressive enfeeblement of the contractility of the vessels advance simultaneously with progressive insufficiency of the myocardium, and it is, in reality, a cardio-vascular weakness. In the second case, on the contrary, it is the exaggerated vascular contractility which predominates, and constitutes the principal danger by suddenly augmenting the peripheral resistance and imposing on the heart excessive work, to which it succumbs because of its already altered structural elements. Hitherto the heart was sufficed for moderate work, but the time arrives when, for a cause still unknown, but, without doubt, due to the irritation of the sclerotic process in the arterioles, the latter contract and cause acute dilatation of the heart. In such cases vasodilators and depressors of arterial tension are indicated, and often free venesection, which may be followed by almost marvellous results.

Obstacles to correct diagnosis in diseases of the myocardium are frequently large, if not insuperable. The physical signs are often obscure and misleading; but there are three important stages in the various myocardial disorders which admit of quite definite conclusions, based upon the rational and physical signs. I refer to hypertrophy, dilatation, and cardiac insufficiency or cardiac weakness. Hypertrophy is, of course, never to be regarded as a disease, and treatment in cases of hypertrophy must be directed to its cause.

Dilatation, whether secondary to valvular disease or dependent upon degenerative changes in the myocardium, offers a larger opportunity for thoughtful consideration with reference to prognosis and treatment. Acute dilatations, associated with acute diseases or occurring in the course of the anemia of young women, are comparatively free from danger. When the dilatation is secondary to aortic obstruction, the danger is much increased, the prognosis is much more grave, and the results of treatment are very unsatisfactory; but when the dilatation is the expression of a gradual change, the result of an influence inducing progressive departure from normal condition (and such influences abound in the largest degree in arterio-sclerosis), any improvement is but temporary.

Cardiac weakness observed in connection with myocardial disorder originating in excesses, from diatheses (whether specific, gouty or rheumatic), or from the poisons of lead, malaria or alcohol—if in any important sense associated with acute inflammatory disease—must, of necessity, give rise to the gravest apprehensions; and it is in just such circumstances as those mentioned that a very large percentage of the deaths recorded of late have taken place.

I hardly know how to express myself with reference to the subject under consideration better than by a brief recital of the circumstances of a single case, which made a profound impression upon a large circle of friends and acquaintances, as well as upon the attending physician. Similar cases, undoubtedly, have occurred in the experience of each one present tonight.

Mr. I., forty-one years of age, well known for years as a man of apparently robust health, formerly active, latterly indisposed to make much exertion, living in a fashionable hotel, and yielding to the temptations of the table (but not intemperate in the use of alcohol), had, within two years, grown fat and soft, increasing

² May 26, June 2, 1888.

his weight from one hundred and sixty to two hundred pounds.

In January he had the "influenza." Two weeks after, he consulted me for the first time professionally, for general debility, dyspnoea on exertion, and occasional attacks of palpitation, with substernal pain.

No explanation of his condition could be offered him other than heart-weakness and general debility, growing out of *la grippe* and his rapid increase in weight. A few days later he had a slight chill; the same evening, a small patch of catarrhal pneumonia in right lower front; the next day, another chill, and slight increase in the broncho-pneumonia; that night, a sudden and rapid rise in pulse-rate (136, 146, 160), a general pulmonary oedema, cyanosis, unconsciousness, and, before morning, death.

Dr. Whittier exhibited the following sphygmograms, as showing the different characters of the pulse-wave in various forms of heart-failure.

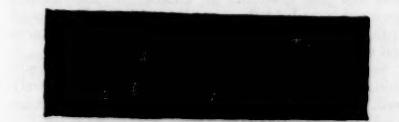

Tracing in condition of Heart-Failure — typical (sharp rise, sudden fall, slight sustaining power).

A CASE OF RUPTURED INTESTINE.

[Under the care of Dr. Conley.]

REPORTED BY H. F. LEWIS, M.D., CHICAGO.

CHARLES B., aged twenty-eight, American, while tending a circular saw, was struck in the right side of the abdomen by a flying piece of plank. He was thrown several feet, did not lose consciousness, but was unable to rise or to move without great pain. Shortly after the injury he vomited. The vomitus consisted of the ordinary contents of his stomach. About three hours afterwards he was brought to the Cook County Hospital, and was admitted to the service of Dr. Conley. When I saw him he seemed to be in great pain, lay on his left side with his legs drawn up, tossing nervously and screaming. There was great tenderness in the right lumbar and right umbilical regions, less in the rest of the abdomen. The abdomen was not swollen, but its walls held as tense as a drumhead. There was no ecchymosis. His pulse was not fast, and of good strength. Percussion and palpation were negative, revealing no tumor and no effusion of fluid. The urine, drawn by catheter, was of normal appearance. There was absolutely no sign of shock. His temperature was normal, and his only symptoms were pain and tenderness. There was occasional vomiting, but he retained part of the liquid nourishment given him. He took one-half a grain of morphine during the evening, and slept fairly until morning, when he again had severe pain. He received one-quarter of a grain more, and thereafter did not suffer. His pulse and general appearance remained good all the morning.

In the early afternoon his pulse was found to be 126, and not so strong as earlier; temperature 101.8°, and a rather quick respiration.

At 4.30 P.M. his pulse was 120 and weak, his temperature 98.6°, and respiration 54. His expression showed visible signs of shock.

At 8 P.M., under ether anesthesia, Dr. Conley made a median incision into the peritoneal cavity. A fetid yellowish watery fluid escaped, and a few melon seeds. The intestines were reddened, and covered in many places with a fibrinous exudation. Pulling out a loop of the ileum, the operator found a rent about one inch long, with ragged and contused edges. This was closed by a continuous Lambert suture of fine silk. There were also several small areas of ecchymosis in the neighboring intestinal wall. The abdominal cavity was irrigated with atomized boric acid solution until the fluid came away clear. A glass drainage-tube was passed to the depth of the pelvis, and an absorbent dressing applied. Time of operation, one and a half hours. The patient was ordered frequent stimulation per rectum and hypodermically.

At midnight of the second day the temperature was

102°, at which point it remained until 10 A. M. of the third day, when it dropped to 99.5°. The patient died at noon of the third day, sixty-eight hours after the injury and sixteen after the operation.

At the autopsy was found a general purulent peritonitis, some ecchymosis of the parietal peritoneum in the right lumbar region, several points of ecchymosis in the wall of the ileum about two feet above the colon and the line of the intestinal suture. The closure was found to be complete.

The features of this case were the continued good pulse, normal temperature, and absence of tympanites or other symptom of such extensive peritonitis as the operation showed to exist. All of his earlier symptoms might easily be accounted for by contusion of the abdominal walls or concussion of the solar plexus.

In the "Transactions of the London Chemical Society," xxi, 1888, are related several recent cases of rupture of the intestine without external wound. In one case a wagon-wheel ran over a man's abdomen. Death in 48 hours. Autopsy showed an opening in the small intestine as large as a silver quarter, and much contusion and congestion of neighboring gut. In a second case a young man was struck in the belly by a playmate's head. There were symptoms of local peritonitis in the left iliac fossa. The autopsy showed a collection of pus in that region, and fifteen inches above the cæcum an area of neurosis in the ileum and a perforation.¹ In a third case a man fell on his belly, and soon showed marked symptoms of perforation. Laparotomy 18 hours afterwards. The ileum found torn one-third across its circumference, the mesentery torn to the extent of one and one-half inches, and the omentum in the region of the umbilicus lacerated. An artificial anus was formed at the point of rupture. The patient lived one month, and succumbed to an operation to close the artificial anus.² In a fourth case a man fell ten feet into a hole. He walked to the hospital, was treated for wounds of the eye and elbow, went home a distance of two miles, and returned in the afternoon suffering from severe vomiting and abdominal pain. These symptoms continued two days, and then tympanites developed. Laparotomy disclosed a tear in the small intestine through the serous and muscular coats (sewed by Lembert sutures). Near by was a complete rent one inch long, allowing escape of feces. An artificial anus was made here, opening on the left side on a level with the umbilicus. Death in 2 hours. A fifth case was that of a man struck in the belly. Six hours after the injury laparotomy was performed. Gas and bloody fluid escaped. A tear was found in the jejunum one-half an inch long, and sutured. There was also beginning peritonitis. The patient died in about twenty-four hours.³

Robson advises, in all cases of suspected rupture of the intestine, that a small incision into the peritoneum be made. If gas or foululent fluid be found the diagnosis is made, and more extensive operation is indicated. Lenn's gas test would hardly be indicated, because one would fear to cause a contused and congested portion of intestine, that might otherwise recover spontaneously, to rupture from the presence of the hydrogen.

— Influenza is said to have broken out again in different parts of Germany.

A CASE OF RHINOPLASTY.¹

BY DR. GEORGE COOK, OF CONCORD, N. H.

THE case was that of a woman, white, aged thirty-eight; married; American; occupation, house servant.

September 19, 1887, admitted to hospital with following history: Seven years previous she received a blow over the nose with the large end of a whip. Pain and swelling followed, abscess formed and pus and pieces of bone discharged. This continued for two years, when the nasal bones and the osseous nasal septum had become entirely destroyed. The tip or cartilaginous portion of nose remained, and there was an elliptical opening one inch long by one-half inch wide.

For five years previous to her admission to hospital she had been in the habit of wearing a piece of adhesive plaster cut to just fit on the edge of the opening. There were also two openings in the hard palate, which were quite small. She states that at the time of receiving the blow she was pregnant. She had had two miscarriages before, but this went to full term and the child is alive now, being ten years old, but has always been feeble. She also states that previous to the blow she never had any humor or sores about her. She had been under the care of different physicians and all used some form of specific treatment. While the blow may have been the exciting cause, some constitutional taint must have been present.

As she had been under a course of iodide treatment before entering the hospital she was put onto hydrargyro-proto-iodide (one quarter of a grain, one pill daily at bed time) and also tincture of cinchona compound (one drachm three times daily).

September 20th, with local use of cocaine we tried to cut away the mucous membrane that had become cicatricial about the holes to hard palate and bring the edges together, hoping to close the holes with mucous tissue; but the bony substance about the palate broke into bits as soon as it was touched, and the mucous tissue was so easily torn that we found it impossible to do much here — indeed we made the holes longer.

The next day, September 21st, under ether we attempted to fill in tissue over the nose. Taking a piece of the adhesive plaster — which by long practice she had learned to cut very accurately — as our pattern, it was placed in an oblique position on forehead so that the pedicle would come near the internal angular process, and the whole tissue down to the aponeurosis of the muscle was dissected up, having a pedicle about one-eighth of an inch wide. Then this new tissue was brought into the gap of the wound of the nose and just filled it. A number of fine sutures were put in to hold the parts in position. The wound in the forehead was drawn together by strong sutures and the whole dressed by iodiform and gauze.

September 30th, the nose graft had become firmly united and the wound in the forehead was entirely well. The patient was kept in the hospital for some weeks under specific treatment.

¹ Reported at the meeting of the New Hampshire Medical Society, June 16 and 17, 1890.

Dr. G. A. Young of this city made an artificial plate for the mouth, which keeps the food from getting into the nasal cavity, and enables the patient to talk much better.

SUFFOLK DISTRICT MEDICAL SOCIETY.

H. F. VICKERY, M.D., SECRETARY.

ANNUAL Meeting, Saturday, April 26, 1890, the President, DR. G. W. GAY, in the chair.

DR. E. N. WHITTIER read a paper on

HEART-FAILURE.¹

DR. F. I. KNIGHT: Dr. Whittier has presented the case so fully and clearly that little remains to be said.

In regard to the frequency of returns at the City Hall, of death from heart-failure, I think perhaps we might put a little different interpretation upon a great many of those cases from what Dr. Whittier did, that is, it is the fashion to call cases of sudden death cases of heart-failure. It is something I regret very much, and have almost decided never to use the word at all. I get disgusted with the constant repetition of this term in connection with cases to which evidently it ought not to be applied, and I think a great many of the returns will be found to be made by men who are ignorant of diagnosis and who are very glad to have this term to get behind. It does not convey any more idea of what the patient died of than to say he died of "heart disease." I do not think it is any improvement. It covers cases of thrombosis, of sudden pulmonary oedema, etc. But it is certainly true that legitimate cases of degeneration of the myocardium are increasing in the community to an alarming extent, and due probably to fast living. You see it in just the kind of people who have other degenerative diseases, Bright's disease, etc., and the last picture Dr. Whittier drew is one constantly occurring, and that is the one class of cases which we feel the surest of,—men somewhat advanced in life, complaining only of dyspnoea on comparatively slight exertion, having anginal pains and perhaps a little irregularity, but with no marked physical signs. Those are the cases in which we should be very guarded in our prognosis. During this past winter I have had two or three patients who have died very suddenly. One was recently reported, correctly I think, as dying of heart-failure, in New York. I had seen him just previously and given a very doubtful prognosis to the friends. It is a class of cases which is increasing, and one which we should look out for.

DR. H. S. SOULE: I fully agree with the gentleman who has just taken his seat, and will only add that I have seen quite recently three cases reported as heart-failure, and at the post-mortem the heart, to all appearances, was pretty healthy, but the right lung and part of the left were not only congested but completely filled up. Two of these cases were reported as deaths from heart-failure and the other from heart-disease.

DR. G. W. GAY reported a

CASE OF GASTROSTOMY.²

DR. WARREN: I have on one occasion had an

opportunity to perform gastrostomy, as I believe also Dr. Gay himself has on one occasion previous to this. My operation was done several years ago, and as it has already been published it is unnecessary to go into details: suffice it to say that the patient lived about four months. I was not very well satisfied with the operation. The great difficulty in the management of the case, after operation, consists in keeping the food in the stomach, according to my experience, so that it shall not leak out again. That is stated to be the case in a number of reports of similar cases. Patients are usually afflicted with a more or less troublesome cough. There is great emaciation usually, and the abdominal walls sag inwards as the patient lies down, the cartilages of the ribs being prominent. When he coughs the walls, instead of being dependent, bulge out in a dome-like manner, at the apex of which is the artificial opening through which food or other contents of the stomach are expelled. The method usually adopted for overcoming this difficulty is the one Dr. Gay used, namely, making a very minute opening so that the bulging mucous membrane will practically close it. I attempted at first to keep a catheter in the stomach, but there was a tendency for the opening to contract. Finally I got considerable relief by making the opening still larger and introducing a sort of dumb-bell shaped tube, so that when an expulsive effort was made in coughing the inner portion would act like a valve. This worked tolerably well. At times, however, there would be leakage and the clothing would be saturated with the contents of the stomach, so that although the patient was up and about and in comparative comfort I felt that modern surgery ought to give us something better than the operation of gastrostomy as it is now performed for the relief of this disease. I made a number of experiments after that, on animals, based on the condition which is reported to have existed in the stomach of Alexis St. Martin. He lived fifty years with quite a large wound in his stomach, for the reason that the mucous membrane was in a dependent fold on the inside of the fistula, and formed a valve which prevented the expulsion of the food during distension of the stomach. We do not hear any reports of his being disturbed by leakage of the fistula. I succeeded in reproducing this valve-like opening in a dog. A tuck was made in the front wall of the stomach, a portion of the stomach cut and lifted up so that when the opening was subsequently made there was a fold of two thicknesses of the stomach wall immediately over it, which, when pressure was exerted from within, prevented leakage of the orifice of the opening. A large dog arranged in this way ran about comfortably with fluids in considerable quantity in his stomach without leakage. On passing a probe through the opening and lifting up the valve milk would dribble out on the floor, showing that there was such a valve there, and after killing the dog and examining the place the valve was found to exist. I had some difficulty, however, in preserving this condition of things indefinitely, because the fistula, if left to itself, contracted and healed over as I think it did in that particular case. To overcome that a spool was placed in the fistulous opening, such as Dr. Bowditch uses for his observations on the gastric fluids in animals, but any such apparatus which had a sufficiently large flange on the inside, so that the dog could not gnaw it out with his teeth, was so large that it pushed aside the valve or the valve was

¹ See page 222 of the Journal.

² See page 223 of the Journal.

not competent to cover it entirely and leakage would take place. If it was made small the dog got hold of it with his teeth and pulled it out, or it tumbled in and healed over.

It seemed to me possible that such an operation might be done on the human subject, a fold being caught quickly, lifted up and stitched above, and the opening made in the anterior wall of the stomach without great difficulty. One hindrance in carrying out such an operation as that would be the contracted condition of the stomach in patients who are starving from stricture. The stomach is small, the walls thick and unyielding, and there would not be the pliability to enable one to make such a valve very well. It would require a good many stitches and considerable time to make the valve hold, and I think it would be a difficult and not very practical thing to carry out. Accordingly I turned to other methods of relief in this disease, and at my suggestion Dr. Mixter had imported from London a number of esophageal tubes adapted for intubation of the esophagus, which were devised by somebody in London. They consist of a number of short tubes about six inches in length, with a funnel-shaped opening. There is attached to one edge of the funnel a long thread and an ordinary esophageal tube or whalebone with ivory point, which can be inserted into this cup-shaped funnel. By means of a string the tube will be held firmly against the end of the whalebone, and can be passed down as an ordinary esophageal tube into the esophagus and engaged in the stricture. When it comes so far down that the flange is just at the point of the stricture, the whalebone can be disengaged and withdrawn, the string remaining, coming out of the mouth and being tied around the ear for the purpose of removing the tube when necessary for the purpose of washing. I had in the hospital three cases of stricture of the esophagus, one cancer, the other two strictures due to the action of caustic potash. The method commanded itself to me decidedly. In the case of the cancer it worked very satisfactorily. The patient had lost forty or fifty pounds, was very much emaciated, and experienced great relief and satisfaction on the introduction of this instrument, and gained in weight during the first few weeks after the instrument was introduced. After that there began to be a certain amount of trouble in the management of it. When the instrument was withdrawn it caused a good deal of retching and vomiting and coughing. The operation of withdrawal and replacement sometimes led to a certain amount of febrile disturbance which would confine him to his bed. It did not work occasionally, and had to be left out a week at a time. Wearing it a considerable time dilated the stricture, so that he was able to go without it very well. I wish I had taken pains to follow up this case. I kept the run of him a month or two. He ceased coming to the hospital, and probably died soon after.

The general impression I had from that intubation of the esophagus was that the method was more satisfactory than gastrostomy.

The two cases of stricture perhaps deserve brief mention. In the first case it worked nicely for a little while. When we attempted to withdraw the tube for the purpose of washing it, it would not come. The patient had pain in the region of the epigastrium and some febrile disturbance. Strong traction failed to bring it, and then it was left alone, and after about a

week the string was cut and the tube abandoned. The statement made by its inventor was that when the tube was passed through the stricture, it could go through the intestinal canal without difficulty, and although I think it took two or three months to do it, it finally passed through, the patient experiencing no disagreeable symptoms from the process. After that we contented ourselves with keeping the esophagus dilated with esophageal bougies.

Another patient had great relief from temporary use of the intubation method, and after that he was very well contented, became an out-patient and visited the hospital occasionally, to have the esophagus dilated with esophageal bougies.

I should recommend a thorough trial of this method. In three cases in which I have tried it it has led to no dangerous results, and has been productive of great comfort to the patient.

DR. RICHARDSON: There will remain a certain number of cases of stricture of the esophagus which cannot be treated by the intubation method which Dr. Warren has described. The tubes which Dr. Mixter imported were used first on the case—I think a case of corrosive poisoning—which entered my service, and they worked very satisfactorily, but that stricture could be dilated very easily at that time by the passage of the esophageal probang, and I think the other cases could. I would like to know what can be done in the way of intubation where nothing can be passed through. We see such cases from time to time. I have had no experience in passing this instrument, but I should infer that it could not be introduced in certain cases and could not be used.

As to the question of prolonging life by opening the stomach, I think Dr. Gay has given his opinion and experience as unfavorable to performing that operation. I think we are constantly meeting that very condition not only in cancer of the esophagus, but also in cancer of the large intestine, in the malignant stricture of the sigmoid flexure, and the question is certainly discussed with us constantly at the Massachusetts Hospital as to the advisability of prolonging life by such an operation as that of artificial anus. I think the two conditions are very similar, the objections very similar, and the results very similar.

The objection to both operations is the discomfort caused by the expulsion of irritating juices from the stomach. The same is true either in the lumbar operation or in Littré's operation, and hence the view taken by many men that neither operation is justifiable, that we are merely prolonging the patient's misery, and that he ought to be allowed to die in the first place as comfortably as possible. I agree with Dr. Gay that not only in stricture of the sigmoid flexure, but in stricture of the esophagus, we ought not to let the patient die, when he may have possibly six months or a year, or in some cases several years of comparative comfort. I never had any experience with gastrostomy, either with the relief that it gives or with the discomfort that attends it, except in the case referred to by Dr. Warren. That patient I saw very frequently, and his life was prolonged. He suffered a great deal of discomfort, and yet his suffering from the disease itself and from the starvation which accompanies it was very much relieved. I think that in both these conditions we are justified in operating, and that it is our duty whenever the patient wishes it, but I think it should be left with the patient and his friends to decide

about prolonging life by these operations. I do not think it would always be as difficult as it proved to be in Dr. Warren's case, to retain the contents of the stomach.

In all the cases I have had of stricture of the oesophagus the patients have declined to have any operation done, and I have watched them die with the suffering which necessarily attends malignant disease—suffering in comparison with which the discomfort of opening the stomach or of an artificial anus is very slight.

In a discussion at the International Congress at Washington on the allied subject of lumbar colotomy the opinion expressed by most men was favorable, and that by making an opening in the intestine in cancer of the sigmoid flexure the relief afforded was very great indeed. I think the operation of gastrostomy is a very similar one, and that with more experience we shall be able to perform it more satisfactorily.

DR. GAY, in closing, said: The longer I live the less dogmatic I am on the matter of prolonging life in malignant disease of certain parts of the body. In cancer of the oesophagus, for example, I doubt if we prolong life much in numerous cases by operation. Nor is that a question which needs concern us as much as that of comfort. The days of one afflicted with cancer of the gutlet are numbered, and it is of comparatively little moment with many persons whether they live three months or six months or longer, but it is of supreme importance that the latter part of their life be made as comfortable as possible; that the pangs of hunger, and the torture of prostration and restlessness be mitigated. In other words it is the surgeon's duty to make his patients as comfortable as possible while they do live, rather than to prolong life at the cost of great and unavoidable suffering.

While no one is justified in basing any conclusions upon the experience of one case, I cannot but feel that my patient was much relieved by the operation of gastrostomy. I doubt if he lived any longer, perhaps not as long by reason of the operation, but under similar circumstances I would advise, and do it again. Intubation is doubtless a valuable method in some instances, but in others it is not efficient, and while a fistula is not as good a measure as we could wish, yet it is the best we have at present.

Recent Literature.

The Cerebral Palsies of Children. A Clinical Study from the Infirmary for Nervous Diseases, Philadelphia. By WILLIAM OSLER, M.D., F.R.C.P., London; Professor of Clinical Medicine in the University of Pennsylvania, etc. 8vo, pp. viii, 103, with six illustrations. Philadelphia: P. Blakiston, Son & Co. 1889.

These admirable lectures on a class of affections even now rarely recognized were delivered two years ago, at the Infirmary for Nervous Diseases, and were afterwards published in the *Philadelphia Medical News*. They are based on a study of 151 cases at the Infirmary, and at the Institution for Feeble-minded Children at Elwyn. Of these cases 120 had hemiplegia, 20 double hemiplegia, and 11 paraplegia. Of the 120 cases of hemiplegia, 57 were boys and 63 girls, 68 cases were right hemiplegia, and 52 left; the greatest

number occurred before the age of three. The first chapter is devoted to the etiology, the infectious diseases, convulsions and trauma playing the most important part. In nine of the cases forceps were used at birth, and the paralysis is regarded as due to their influence. It seems questionable, however, whether the forceps must be made responsible for such conditions; for the pressure upon the cranium in cases of protracted labor or in irregular presentations must certainly do more harm than the temporary pressure of properly-applied forceps, especially if they are used before the pressure of a narrow pelvis has been too protracted. The second chapter is devoted to the symptoms of hemiplegia, illustrated by representative cases. Little is said of the significance of initial and repeated convulsions as an indication of a cortical lesion. Like most observers, Osler finds aphasia a rare symptom, only thirteen cases of speech disturbance being noted. Mental weakness, except among the Elwyn patients, was noted in only ten per cent., which Osler thinks may be due to the fact that the majority of the patients were seen in the early stage. Clasp-knife rigidity and cross-legged progression with irregular and ataxic movements, were the commonest conditions noted in diplegia. In common with most authorities now, Osler holds that, at least in the majority of cases, the spastic paraplegia of childhood is of cerebral origin. The chapter on pathology is, necessarily, unsatisfactory. The writer has dwelt too little on the distinction which sometimes can be made between cortical and basal lesions. The former are probably the commonest in the cerebral palsies of children, and, as a result, we find sclerosis or parencephalus—the effects of a still obscure cause. Osler holds that the most important processes are hemorrhage, occurring during violent convulsions or during a paroxysm of whooping-cough; post-febrile processes, embolic, endo- and periarterial changes, and encephalitis; and thrombosis of the cerebral veins. Strümpell's polioencephalitis he holds is still doubtful. Hemorrhage he regards as chiefly meningeal, intra-cerebral hemorrhage, from causes similar to those in the adult being comparatively rare; and venous thrombosis is still doubtful. The prognosis is doubtful, and complete recovery is probably extremely rare, the hand seldom regaining the power to make fine movements. Massage, Faradism, and orthopedic measures give the best results in treatment; and, in addition, careful education in feeble-minded patients will often give good results. Brain surgery, except in some cases of cortical epilepsy, is considered to be of no value.

P. C. K.

An Experimental Study of Lesions Arising from Severe Concussions. By B. A. WATSON, A.M., M.D. 8vo, pp. 76, with one illustration. Philadelphia: P. Blakiston, Son & Co., 1890.

The attention paid to the study of the traumatic neuroses makes this study of peculiar interest at the present time. The experiments, 141 in number, were performed on dogs, and consisted in dropping them from a height of twenty-five feet, so that they struck the nates or the spine. The symptoms which followed were carefully noted, and an autopsy was made a few days after. In fifty cases the cerebro-spinal axis showed pathological changes, in fourteen cases this change was primary. There were also very frequently noted traumatic lesions elsewhere, fifty times in the lungs, twenty-two times in the liver, thirty-six times in

the kidneys, and fourteen times elsewhere. In forty-one cases no lesions were found.

The writer points anew to the fact that the anatomical position of the cord is a great protection against injury. His conclusions are as follows: "(1) Concussive accidents never produce pathological changes in the spinal cord, except when great force has been applied to the spinal column, and these cases are generally, if not always, complicated with a fracture of the body of a vertebra, dislocation of the same, rupture or stretching of vertebral ligaments, or severe lesions in other parts of the body, which terminate quickly in death. (2) The symptoms indicative of these morbid changes are immediately developed, rarely become intensified by reason of morbid changes occurring in the spinal cord — exceptional cases being limited to fractures and dislocations, or those in which a slow hemorrhage occurs, causing pressure on the cord. (3) It is frequently very difficult to diagnose stretching of the vertebral ligaments on the living subject, and there are ample reasons for believing that this lesion is frequently overlooked in post-mortem examinations. (4) Injuries of the spinal cord, complicated with lesions of organs in the thoracic, abdominal and pelvic cavities, develop symptoms dependent on the *existing complication*, and the termination of these cases rests on the character of the traumatism. (5) Concussive force, although remotely applied, frequently results in the production of severe and even fatal traumas in various organs within the thoracic, abdominal and pelvic cavities."

It is unfortunate that the experiments have not been better tabulated. Cases in which no microscopical examination was made have been classed with cases with no lesions. No distinction, moreover, has been made in the lesions found in animals, presenting, during life, morbid symptoms, and the lesions or lack of lesions in animals apparently uninjured. In view of the importance of vascular disturbances, as observed in man and emphasized by recent autopsies, too little weight has been given to hyperemic conditions of the brain and cord. It might have been of value, too, to observe the later changes. In only two cases was the animal kept alive beyond a few days. A longer duration of life, in animals that showed signs of injury, might have led to the development of morbid changes which the author has disregarded. Although the experimental work shows evidence of careful study, the summing up of the work is indefinite and apt to be misleading.

A Hand-book of Obstetrical Nursing, for Nurses, Students and Mothers. By ANNA M. FULLERTON, M.D. Philadelphia: P. Blakiston, Son & Co., 1890.

This manual comprises the course of instruction in obstetrical nursing given to the pupils of the training school for nurses connected with the Women's Hospital of Philadelphia, and is based on the teachings of Dr. Anna E. Broome. The book is well written and well illustrated; and its teachings are eminently sound. The chapter on the care of the new-born infant is especially good, and includes explicit directions for artificial feeding. It is an excellent *vade-mecum* for nurses, and medical students would profit by its perusal; but we do not believe in putting such a book into the hands of those about to become mothers. While admitting a difference of opinion as to the advisability of pregnant women reading books relating to their

condition, we firmly believe that the harm done to women awaiting their labor by reading chapters on the accidents and emergencies of the lying-in room, decidedly over-balances the good that may ensue from the reading about the signs of pregnancy and the preparations for the impending event. Women should by all means be taught hygiene and the management of infants; but, in our opinion, the less a pregnant woman knows about the technicalities of child-birth, the better for her mental and physical welfare: such knowledge is for the doctor and the nurse.

Syllabus of the Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By RICHARD C. NORRIS, M.D., Demonstrator of Obstetrics; University of Pennsylvania. Philadelphia: W. B. Saunders. 1890.

This syllabus has been prepared to assist students in the art of accurate note-taking, and to give them a logical and consecutive outline of their work. The book will prove of most use to the students of the University of Pennsylvania, as it is obviously based on the obstetric lectures of that school; but all students of medicine will find the Syllabus of material assistance, as it presents the subject very clearly, fully, and systematically. We are sorry that the University of Pennsylvania has not adopted the new obstetric nomenclature, which was suggested by Prof. A. R. Simpson and approved by the late international congress held in Washington. It is very desirable that nomenclature should be the same the world over; whether in obstetrics or mathematics.

Etudes de Clinique Infantile. Syphilis Héréditaire précoce, Laryngite Syphilitique, Broncho-Pneumonie par Infection Intestinale, Prophylaxie de la Rougeole et de la Diphthérie, à L'Hospice des Enfants-Assistés. Par le DR. SEVESTRE, Médecin de L'Hospice des Enfants-Assistés. Paris: Aux Bureaux du Progrès Médical. 1889.

This pamphlet of 141 pages begins with an exhaustive article on the early manifestations of congenital syphilis. The different lesions of the skin are illustrated by some very good wood-cuts, and this subject, as well as the next article entitled "The Early Laryngeal Manifestations of Hereditary Syphilis," are dealt with methodically and clearly. The third article is an interesting account of some cases of infectious bronchopneumonia where the poison apparently originated in the intestine. The fourth article describes the prophylactic treatment of measles and diphtheria at the Hospice des Enfants-Assistés. All the articles are well worth reading.

The Diseases of Children, Medical and Surgical. By HENRY ASHLEY, M.D., London, M.R.C.P., Physician to the General Hospital for Sick Children, Manchester; Lecturer and Examiner in Diseases of Children in the Victoria University; formerly Lecturer on Physiology in the Owens College and in the Liverpool School of Medicine; and G. A. WRIGHT, B.A., M.B. Oxon, F.R.C.S. Eng., Assistant Surgeon to the Manchester Royal Infirmary and Surgeon to the Children's Hospital. London and New York: Longmans, Green & Co. 1889. All rights reserved.

This work is written after a ten years' study of the cases which, during that time, had been seen at the

General Hospital for Sick Children at Manchester, where over 11,000 children are treated annually. The original feature of the book is that it is written conjointly by a physician and a surgeon. It is not an explanatory treatise, but, being based on experience, is not a mere compilation. There are 138 illustrations, taken mostly from photographs of cases that have been under the author's care. These illustrations add much to the value of the book, as they are unusually clear, and make especially prominent the surgical articles, which are exceedingly well written and practical. Much space is devoted to diseases of the nervous system, and under general diseases the subject of Rickets is clearly written and admirably illustrated. The article on feeding, besides being entirely inadequate in its length to cover this very important subject, is unreliable in its statements, and is remarkable for the bad advice which it gives; it is, in fact, a serious blot on an otherwise fairly written book.

A Manual of Anatomy for Senior Students. By EDMUND OWEN, M.B., F.R.C.S. With numerous illustrations. London: Longmans, Green & Co. 1890.

We do not feel very sure what the author's purpose may have been in writing this book, but we cannot consider it a success. In general terms, it may, perhaps, be called a good book; but there are so many good books on anatomy, that, to be worth much, a book must be very good, and this one is not. We gather that the author felt that applied anatomy, as treated in most works, is too nearly exclusively surgical; and he has meant to include more. We quite agree with him as to the merits of this plan, and he has had some success in carrying it out; but, as a whole, the book is unsatisfactory. The methods are old. The surface anatomy is not up to either Holden's or Thane's. Frozen sections are practically ignored. The illustrations are, for the most part, from other works, and consequently but too familiar, as accuracy has not been regarded as indispensable. Thus, there is an extraordinary figure of the convolutions (from Gray), and what purports to be a representation of a sagittal section through the female pelvis, representing the vagina as a nearly vertical round tube. The text, in many respects, is up to the times. The cæcum, for instance, is said to be, as a rule, entirely surrounded by peritoneum; but, on the other hand, there is no allusion to the division of the old corpus striatum into the nucleus caudatus and the nucleus lenticularis. There is consequently no attempt at a proper description of the internal capsule, and the treatment of the ganglia of the base is beneath criticism. If the corpora quadrigemina are even mentioned, we have failed to find the place. We could point out other deficiencies, but perhaps this is enough. Several of the diagrams are worthy of praise. T. D.

A Handbook of Physical Diagnosis of Diseases of the Organs of Respiration and Heart, and of Aortic Aneurism. By R. C. M. PAGE, M.D. Second edition. New York: J. H. Vail & Co.

The prompt appearance of a second edition of this work shows that it has met with the appreciation which it deserves. The book is clear, well printed, profusely illustrated, and may be recommended as a safe guide to the subject of which it treats.

THE BOSTON Medical and Surgical Journal.

THURSDAY, SEPTEMBER 4, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 233 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMREL & UPHAM,
233 WASHINGTON STREET, BOSTON, MASS.

THE PRESENT STATUS OF BACTERIOLOGY.

At the late meeting of the Berlin Conference of Medicine, August 4th, Dr. R. Koch made one of the opening addresses, "On the Present Status of Bacteriology."

Fifteen years ago, he said, bacteriologists knew of the presence of micro-organisms in charbon, recurrent typhus, and the infectious diseases of wounds, but did not yet impute a serious etiological importance to them. Since then, new methods of research have given to microbiology a rapid development, for which progress we are chiefly indebted to improvements in microscopy, and to the employment of aniline staining reagents, all of which have enabled us to differentiate the germs of disease by means of cultures in various solid and liquid nutrient media.

By pursuing their investigations, bacteriologists have succeeded in identifying new micro-organisms and in establishing, with certainty, their etiological relation to the diseases in connection with which they have been met. It was hoped, after this first success, that we should rapidly accomplish the isolation and identification of the micro-organisms of all the infectious diseases. In this we have been disappointed.

To-day we may consider it as settled that the infecting bacteria are organized living beings, forming fixed and constant species, quite as independent as the vegetal organisms of higher order. They have certain acquired morphological qualities, and are not derivable from fungi, from moulds, or from the lower algae. Moreover, we can deduce from the existence of infectious diseases of great antiquity, such as leprosy, phthisis, the proof that bacilli preserve for ages their characteristic properties. Without doubt, varieties may arise, as in all species, but the former do not lose the principal characters of the species.

On a bad nutrient soil, imperfect forms of micro-organisms may be developed, forms which have lost the properties of the perfect microbes which thrive in living bodies and form toxic substances.

But these varieties remain within limits which are

very restricted, and never constitute a transition from one species to another; thus, for example, the bacillus anthracis never becomes the bacillus subtilis.

To determine the species of a bacillus, it will not do to be content with isolated, fixed or variable characters, but it is necessary to note the greatest sum possible of morphological and biological characters which the species under consideration can present, otherwise, there is nothing but misconception and confusion in bacteriology.

The presence of the bacilli of typhoid fever in the mesenteric glands, the liver, the spleen, cannot give rise to any mistake, because there are never found in those organs, similar bacilli. But we can easily be mistaken in endeavoring to identify the typhoid bacillus in the intestinal liquids, the water, or the air, for these media contain a great number of bacilli which much resemble it. The same mistake may be made with reference to the bacillus of diphtheria, so that it will not do to affirm the presence of a specific microbe in the water, the soil, in sewer pipes, etc., till the findings have been subjected to a rigorous criticism according to the method of exclusions and rejections.

Per contra, it has been possible to establish from the first, for the bacilli of tuberculosis and of cholera, characters which enable us to determine their species with absolute certainty. This result, this rigorous precision of diagnosis, is what we must require in the search for the bacillus of diphtheria and of typhoid fever. It is easy to understand the prophylactic value which a sure differentiation of these infectious agents would give.

Koch next asserts that his researches on the tubercle bacillus have taught him the bounds prescribed by prudence, and the need of extreme caution in these investigations. One can acquire certainty only after the study of the reactions under aniline staining fluids, and after long watching pure cultures and testing pathogenic qualities. He has thus been able to prove that the bacillus of tuberculosis of fowls differs in many respects from that of other animals; this he has shown both by cultivating it and by the results of inoculation. To know whether he had to do here with a special microbe, or a variety of the true bacillus of tuberculosis, he endeavored to produce artificial varieties of the tubercle bacillus by all sorts of procedures. He exposed cultures for many months to high temperatures, amounting almost to the destruction of the bacilli; he subjected them to the action of light, of moisture, of chemical substances, cultivating them in competition with other bacilli; passing them many times through the bodies of animals more or less refractory to tuberculosis.

About a year ago, having obtained a certain number of fowls affected with tuberculosis, he made pure cultures of the microbe; the results were identical with those mentioned above.

The bacilli of the tuberculosis of fowls constitute, then, a different species from those of common tuberculosis, though very near of kin. The recent investi-

gations of Uafucci have confirmed this conclusion. We cannot say that this new bacillus is pathogenic in mass till we have noted its presence in the human organism.

Recent researches have also shed light on the question of the relations of bacteria to the infectious diseases. When we have established that certain bacteria are found constantly in this or that infectious disease, that they are never met in any other, that they can live and be cultivated out of the animal body, and that in this state they are capable of reproducing the disease, their etiological rôle is proved. This demonstration has been made for tuberculosis, erysipelas, tetanus, and many of the diseases of the lower animals.

Per contra, the fact that we cannot reproduce with pure cultures, a disease in animals, is evidently not sufficient to prove that the particular bacillus is not the cause of the disease in man. This is the case with the bacilli of leprosy, of Asiatic cholera, of typhoid fever, of diphtheria, of typhus recurrent.

The study of the following questions has also made great progress: the parasitism of bacteria, their mode of penetration and evolution in the organism, the chemical products (tox-albumins) resulting from their activity, the combinations of several infectious diseases in the same individual, lastly, the subject of immunity. The theory of phagocytosis is, however, losing ground every day.

The study of the action of light and heat on bacteria has given us important results for prophylaxis. Solar light has a destructive action on the bacilli of tuberculosis. According to the thickness of the stratum of the culture exposed to direct sunlight, the bacilli are killed in a time varying from a few minutes to a few hours. Indirect diffused light has a like action, but more slow; cultures exposed to the daylight by a window are killed in from five to seven days.

All bacteria have need of moisture in order to develop, but they cannot quit the medium where they are growing, and are not susceptible of diffusion through the air, except under the form of dust, the product of desiccation.

Bacteriological researches have resulted in much that has been delusive, but also in much that is encouraging. The fact that we have not yet been able, despite indefatigable researches and painstaking, to discover the microorganisms of the exanthematous diseases, proves that these microbes must be sought by methods of another order. Perhaps we have to do in these diseases with microorganisms belonging not to the group of bacteria, but to that of protozoa, like those which have been found in the blood of malarious patients.

As for the practical results connected with bacteriological studies, they are already considerable. Disinfection is performed in a more judicious and effective manner. Potable waters are being examined from the point of view of their infectiousness; the same may be said of milk and other foods; of the air of school-rooms, of sewers, etc. We can now detect at

its commencement, and with almost infallible certainty, an epidemic of Asiatic cholera, and provide in time the necessary prophylactic measures. The early diagnosis of tuberculosis has been facilitated.

From the point of view of direct therapeutic utility for the individual, we can thus far only point to the preventive inoculations of Pasteur against charbon, symptomatic charbon, rabies, etc. As for rabies, it is perhaps not a bacillary disease, but the study of rabies has, at least, developed on bacteriological ground.

But we may hope that even from a therapeutic point of view, bacteriology is entering upon an important future. Much more may be expected for diseases of slow or chronic duration, than for those that run a rapid course. With respect to tuberculosis, however, all the germicide agents thus far employed have been unavailing. Koch affirms, however, that after numerous experiments he has found certain substances which are capable of preventing the development of tubercle bacilli. Among such are the essential oils, certain aromatic compounds, such as naphthol Eamine, paratoluidine; certain aniline coloring-matters, such as fuchsin, methylene blue, gentian violet, auramine; then mercurial vapors, and the compounds of silver, and especially of gold, with hydrocyanic acid. Thus, the cyanide of gold in a solution of 1 to 2,000,000 arrests the multiplication of the microbes in cultures out of the animal organism.

In animals, these substances do not avail in arresting the progress of the disease. Of late, however, Koch says that he has succeeded in finding certain compounds which have shown themselves to be prejudicial to the bacilli when given internally to tuberculous animals. Guinea pigs, which had been dosed with these substances, remained refractory to the inoculation of tuberculosis. In others, previously infected, the disease was seen to undergo retrogression.

If it should be confirmed that there are germicide agents capable of arresting the progress of tuberculosis in animals, we shall gain courage to hope for what is at present the great desideratum from applied bacteriology, the arrest or at the least the prevention of tuberculosis in man.

MEDICAL NOTES.

—The gold medal of the British Medical Association was conferred upon Surgeon Parke of the Emin Pasha Relief Expedition at the annual meeting of the association on July 21st. The recipient was given a most hearty and enthusiastic welcome by the association. Mr. Stanley, who intended to be present, was prevented by illness.

—The ordinary obstetric fee in the interior of China, according to a writer in the *Medical Missionary Journal*, is among the better classes two dollars, when the child proves to be a boy, one dollar for a girl. Among the poorer one dollar for a boy, and fifty cents for a girl.

—Virchow extended the following cordial welcome to the American delegates of the International Congress, according to the *Medical News*: "We in Germany have great admiration for the American medical world, which, to-day excels in surgery, midwifery, and dentistry. I can say for myself and colleagues, that the American contingent will be honored and heartily welcomed. We admire their scientific zeal, and begrudge them their extraordinary skill, and shall try to imitate their push and energy. I find these latter virtues in the American student as well as in the finished scientist. My German students generally spend a few semesters deciding what line of medicine they shall follow, while the American student walks into the arena with a fixed purpose, and an indomitable determination to accomplish it. This is why your men secure the laurels before their hair turns gray. My friend, Dr. H. Wood, of Philadelphia, will be the speaker for the Americans at the coming Congress. He is sure to do himself and the great city and country from which he comes, high credit."

—Among curious marital customs referred to in a recent paragraph in the *Popular Science Monthly* is that known as the *covade*, which has been a favorite subject of ridicule for centuries, consisting in the father, on the birth of his child, making a ceremonial pretense of standing in a relation to it similar to that of the mother. He is nursed and taken care of, and performs such rites as fasting and abstaining from certain kinds of food or occupation, lest the new-born should suffer thereby. This custom is known in the four quarters of the globe. How sincerely it is still accepted appears in a story of Mr. Im Thurn, who, on a forest journey in British Guiana, noticed that one of his Indians refused to help haul the canoes, and on inquiry found that the man's objection was that a child must have been born to him at home about this time, and he must not exert himself so as to hurt the infant. In the Mediterranean district the *covade* has prevailed even into modern times.

—Dr. Tyson records, in the *University Medical Magazine*, a unique and successful treatment for hysterical vomiting. A young girl, fourteen years of age, insisted that she vomited everything she swallowed, even water. Her statements were found to be true. She had every manner of treatment applied, systematically and locally, but to no purpose. She was blistered, and received strong currents of electricity to no effect, and she was finally discharged. She returned a few days after, claiming to be as bad as ever. The resident physician, knowing that all else had been tried, told her emphatically that whatever she vomited she must immediately swallow. To the surprise of all her vomiting ceased, and since this order was given she has taken every sort of food and retained it.

—The planting of eucalyptus trees for the purpose of draining the soil in malarial districts is one which has met with some success, and the British *Medical Journal* cites a new and interesting instance thereof. The Trefontane Convent at Rome had become posi-

tively uninhabitable, owing to the malaria, which attacked, in many instances with fatal results, its inmates. Senator Torelli presented a bill proposing that the estate annexed to the convent should be planted with eucalyptus as an experiment against malaria. The bill was passed, and the Trappist monks planted thousands of eucalyptus plants of all species on the estate. But still the malaria raged, and several monks suffered severely. It was, however, remarked that it was only the monks who had their cells looking on the central cloister who fell victims to the malaria. This suggested the idea of planting four eucalyptus trees at the four corners of the cloister. The plants, sheltered from the winds, soon grew to a great height. The immediate result was the complete draining of the soil in the cloister, and the disappearance of malarial fever from the convent.

BOSTON.

— The caterer who supplied Camp Philip H. Sheridan, in which were entertained nine or ten thousand of veterans during the recent Grand Army celebration in Boston, has been brought into court on complaint of Dr. Charles Harrington, inspector, for selling to the veterans adulterated milk.

— The Boylston Prize, of the Harvard University, for 1890, amounting to \$200, has been awarded to Dr. H. A. Hare, for an essay entitled, "The Uses and Value of Antipyretics in the Treatment of Fever."

— The foreman of the gang of trackmen who, while at work on the Old Colony Railroad, by leaving a jack under the rail caused the recent disaster at Quincy, has been arraigned for manslaughter, and in the preliminary examination has pleaded not guilty.

Miscellany.

ANTISEPTICS AND ANÆSTHETICS AT BERLIN.

It was evident on all sides at the Berlin Congress, remarks the *British Medical Journal*, that antiseptic, or rather aseptic, surgery is held in the very highest repute in that city. A glance at the operating theatre of any hospital — such as that of the Moabit, in which Professor Sonnenberg has charge of the surgical wards — was further sufficient to show the extreme care taken, and the lavish expenditure that had been incurred so as to render all wounds perfectly aseptic. The surgical instruments are all kept in cupboards constructed solely of glass and iron, and consequently perfectly washable throughout; the scalpels are all entirely composed of one piece of metal, a method that renders it impossible for dust or dirt to collect between the blade and handle; the operation table is constructed of one slab of light green glass about an inch thick, placed upon an iron frame, and running upon wheels with india-rubber tires; and in offices adjoining the theatre are ovens for the sterilization, by means of dry or moist heat, of everything (bandages, cotton wool, and dressings of all kinds) to be

applied to wounds, or for use during the surgical operations. The surgeon exhibited the dress worn by him during operations, which included even goloshes. In Professor von Bergmann's clinic, too, in the Ziegelstrasse, similarly minute precautions are constantly observed. But in spite of the efforts to excel by this extreme attention to the details of antisepic surgery that were everywhere observable, our contemporary expresses proper disappointment to learn that chloroform is still constantly employed for the production of general anesthesia during surgical procedures, not only in Berlin, but throughout Germany, and hopes that Dr. Horatio Wood's powerful address in favor of ether may direct attention to the compounds such as ether and the A. C. E.

INFREQUENCY OF SYPHILIS IN ENGLISH COUNTY PRACTICE.

ALFRED FREEER, President of the Birmingham and Midland Counties Branch of the British Medical Society, in a presidential address, speaks as follows of his experience with syphilis:

"I am old enough to remember M. Ricord's instructive and oft amusing lectures under the trees of the garden at the Hôpital du Midi, when he used to operate *sub die* early in the morning. At that time one could not help looking at the world through a syphilized atmosphere, and when I came to country practice I found plenty of examples of the old scourge; but for many years past I have seen less and less of syphilis, so I suppose the nymph is beginning to take up residence more exclusively in cities and large towns; or perhaps she is shy of appearing before greybeards. Her prime exhibit, the true Hunterian chancre, on which the great Ricord used to expatiate so eloquently, has almost gone from my gaze. It is a matter for national congratulation that, owing to the improvement in habits of cleanliness among the people, if not to improved morality, this disease is far less virulent than formerly, even in our large centres."

POISONING IN THE BOMBAY PRESIDENCY.

DR. COLLIS BARRY's report of the operations of the Chemical Analyst's Department, last year, in the *Indian Medical Gazette*, June, 1890, throws, as usual, an interesting side-light upon the crime of the Bombay Presidency. There were 170 cases of suspected human poisoning, and poison was detected in sixty-six cases. It is curious to notice that the long-standing preference of the poisoning class for arsenic continues, just half the cases detected last year being cases of arsenic poisoning. Opium comes next, with twenty cases; pounded glass was used in five cases, and datura in two only. Only a minority of these cases were homicidal, and in these the mixing of poison with sweetmeats seems to have been the favorite method of accomplishing the poisoner's purpose. In one case the murderer determined to employ an accredited brand, and used "Rough on Rats." Pounded glass, one of the favorite preparations of the Italian poisoners in the Middle Ages, was only ineffectually employed, for though all the cases were apparently attempts at homicide, none of them succeeded. The preparers of pounded glass, however, seem to be bun-

giers at the art. In a case at Dhulia, for instance, the intended victim at once detected the plot by the grittiness which he noticed in the bread in which the glass had been placed. In a case at Kalyan green glass, probably a crushed bangle, was put in some rice, but the victim noticed the green particles before eating his food. At Nasik a woman confessed to having pounded her bangles and put the dust in her husband's food.

THE TREATMENT OF PSEUDO-MEMBRANOUS LARYNGITIS BY MERCURIAL FUMIGATION.

A PAPER on the above subject, by Dr. George E. Law, in the *Brooklyn Medical Journal*, August, 1890, gives the favorable experience of the author in this mode of relieving laryngeal stenosis in croup. He believes it will often obviate the necessity of operative interference. The method of its application is thus described:

The apparatus consists of a tent, and an alcohol-lamp with arms, to support a piece of sheet-iron. A good tent may be quickly constructed in the following manner:

"Each post of a child's crib is extended by fastening to it in an upright position a bed-slat. The frame is completed by cross-pieces above. Sheets to cover the frame complete the tent. The child is placed in the crib at one end, the lamp is lighted, the sheet-iron plate is adjusted and heated, and thirty grains of calomel are dropped upon it. The lamp is then placed under cover at the end not occupied by the child. The vapor quickly rises and fills the tent. The usual time of each treatment is ten minutes, but may be varied if circumstances indicate.

"The attendants should be cautioned not to inhale the fumes unnecessarily, as mercurial poisoning is quite certain to result. In the patient, however, this effect does not follow.

"The temperature and humidity of the room should be as with any other treatment in the same disease. It is well to have the use of two rooms, reserving one to be used only while the treatment is in progress, and thoroughly airing it after using.

"Usually at first the treatment should be repeated every two hours, increasing the interval as the period of relief extends. If the patient is weak it is well to give a stimulant before treatment.

"The prompt relief of stenosis he supposes to be due, partly at least, to the relaxation caused by the treatment, just as we see relief follow an emetic in membranous croup, even if no membrane is expelled. The cure is due both to the local and to the constitutional action of the drug."

ANTISEPTIC CEMENT FOR PROMOTING BONY UNION.

THE Berlin correspondent of the *Therapeutic Gazette* (August 15th) writes of Prof. Thomas Gluck, the newly elected director of the Children's Division of the Kaiser and Kaiserin Friedrich's Hospital, and of the methods of promoting the union of bony surfaces, by means of an antiseptic cement.

The cement has been used by Professor Gluck to unite the smooth or rough ends of bones to each other. The serrations are touched with the thermocautery at a white heat, and the cement, being spread

upon the opposed surfaces, the two ends are then united as quickly as possible. This cement becomes as hard as glass in about two and a half minutes after cooling. Moreover, it can be used not only as a method of uniting bones, but also for packing cavities in them, and it is thus possible to cement a foreign body into the substance of a bone with perfect safety. If, later on, this antiseptic cement forms a hard ring at the point of union, it will behave just like any other trivial osseous enlargement, but with this fundamental distinction, that it is called upon to play an important part in definitely contributing towards forming the fixity of the would-be joint, and also that this immobility is obtained in a careful and systematic manner. In fourteen cases of joint-disease, in which resection was indicated, Professor Gluck has, as a rule, resorted to this method by invagination. In each instance the apparatus has been rendered antiseptic, and recovery has been obtained without inflammation. We have, moreover, to mention in these cases the absolute freedom from pus in the parts concerned, under antiseptic treatment; the perfect immobility of the union; the immediate recovery of the original length, as well as the nearly natural subsequent growth of the limb, which is always so desirable in orthopedic operations. In addition to the safe union of such foreign bodies, as the ends of different bones, this method allows every conceivable mode of treatment, and the use of any apparatus, as well as its own applicability to troubles in all parts of the body, whether resulting from diseases of the osseous system, dislocation, or ununited fractures.

TREATMENT OF OBESITY.

PROFESSOR HEINRICH KISCH gives the following principles as those which govern his practice at Marienbad in the treatment of obesity (*Therapeut. Monatshefte*, No. 5, 1890, and *Practitioner*, August, 1890):

(1) The avoidance of superfluity in the ingestion of food, — it is desirable that there should be a decrease of *quantity* to an amount smaller than what the patient was accustomed to, but yet inside the lines within which the body can be sustained. In plethoric individuals, 160 grammes albumen are given, 10 grammes fat, and 8 grammes carbohydrates; and in anemic patients, 200 grammes albumen, 12 grammes fat, and 100 grammes carbohydrates. There may be three or four meals daily at fixed hours, but nothing in the intervals.

(2) As to the *quality*, the principal point is a full protein meal, corresponding to the nutrition and condition of life of the individual, and having regard to his age, stature, occupation, and habits, with a moderate amount of carbohydrates, and the fat reduced to a minimum.

(3) Ingestion of fluid is not limited; particular drinks are allowed according to need, only during meal-times little or nothing ought to be drunk. To lessen thirst and encourage diuresis, the use of alkaline carbonate waters is advised. Anemic patients should drink less water than plethoric people, and the same remark applies to those with cardiac insufficiency.

(4) Bodily movements must be methodically carried out, for example, exercises, walking, mountain-climbing, with particular care as to the existence of

fatty heart. By these means the mental condition may be improved.

(5) Sleep should be curtailed to six or seven hours by night; and sleeping by day, especially after meals, is forbidden.

(6) Stimulation of tissue-change is secured by a bath of average temperature and cold rubbing; where no vascular disease, vapor baths followed by cold friction may be permitted. The bowels should move regularly and in sufficient quantity daily.

The following diet table is carried out at Marienbad by Professor Kisch's patients: In early morning, five to six o'clock, three to four glasses of Marienbad water; then a walk through the wood for one or two hours; after which, *breakfast*—cup of tea or coffee with one tablespoonful of milk; without sugar, some biscuit, a little cold lean meat (roast beef or veal) or ham deprived of fat; no butter. Between 10 and 11 A.M., a Marien-spring bath, with the addition of soda, for fifteen minutes, after which, cold rain douche; then an hour's walk and one glass of the Wald-spring with lemon-juice. Where the heart is intact and powerful, and no arterio-sclerosis, a vapor bath with a cold rub down following, may be allowed twice a week. *Dinner*, between one and two—no soup, or one of thin, not fat, beef juice without addition of barley, sago, bread, etc.; roast lean meat, beef, veal, food without sauce, having vegetables, spinach, cabbage, cauliflower, bread-crust; and for dessert, a little fresh fruit. Forbidden are goose, duck, pork, carp, salmon, herring, puddings, potatoes, butter, cheese, sweet preserves, cream and ices. As a drink, one wine-glassful of good light wine may be given, the best time being an hour after meals; no beer, no champagne, no liquor. Walking exercise for three hours; then one cup of coffee or tea without sugar or milk; and about 6 P.M., a glass of Marienbad water. *Supper*, about seven or eight o'clock—100 to 200 grammes of roast meat, cold roast, or lean ham, and a little bread-crust. A walk for one hour after. Before bed-time, cold sponging of the body.

PAVY ON THE TREATMENT OF DIABETES.

DR. F. W. PAVY read an article on the subject at the recent meeting of the British Medical Association, which, while not advancing any novel theory, presents clearly and with the authority which the writer has been conceded to have on the subject, the reasons for, and the importance of, the dietetic treatment of the disease. After speaking of the function of the normal liver in intercepting sugar from entering the general circulation, he says:

"Sugar reaches the general circulation in a manner that it ought not, and to its presence in the system are due the various symptoms belonging to diabetes. Through reaching the general circulation it becomes eliminated by the kidney and is lost. The disease thus involves a sacrifice of material which ought, by rights, to be turned to account, but this is a point that has but little bearing on the production of the phenomena that are observed in connection with the disease. If it were only a question of waste of the carbohydrate principles of food, there would be no reason against their being taken and allowed to run off. Provided a sufficient amount of other alimentary principles were consumed to meet the requirements of life,

no particular harm need arise from the sacrifice of the material occurring. What, it may be said, in reality inflicts the harm, is the altered constitution of the blood, occasioned by the presence in it of the sugar which passes through the system to the urine. In proportion to the largeness of the amount of sugar thus traversing the system in the blood, so will be the extent of deviation from the natural state, and so in correspondence the impairment of health that will be found to exist.

"The class of cases to which these remarks apply is that in which the discharge of sugar is susceptible of control by treatment, and the class embraces the majority of the cases in which the disease sets in after the middle period of life.

"As long as the passage of sugar through the system is prevented no harm takes place. In the course of all my experience in diabetes I have never known anything serious to arise as a part of the disease so long as the urine has been kept free from sugar. There is nothing, in fact, to form the source of trouble, seeing that there is not the abnormal presence of sugar in the circulation to occasion deviation from the healthy state. On the other hand, when sugar is passing through the system, and the remark applies in proportion to the amount passing through, not only are there to be observed the symptoms ordinarily consequent thereon, but a constant state of insecurity exists, from the danger of the supervention of the serious issues known to follow upon the disease. Moreover, with the unnatural state occasioned by the presence of sugar, nutritive action is not carried on in such a manner as to properly maintain the general strength. As a consequence, the general power becomes sapped and prematurely exhausted, and the system weakened and rendered less able to resist the effect of pernicious influences. Such is not the position when sugar is not similarly traversing the system. Indeed, there is nothing to render the state essentially different from that ordinarily existing.

"The contrast between the two conditions—that is, where sugar is allowed to abnormally exist in the system, and where it is prevented from doing so—is well shown in cases where the disease has run on for some time without being recognized, and is subsequently controlled by dietetic treatment. What will be observed in such instances will be a gradually advancing impairment of health and increasing severity of the symptoms of the disease, and it is right to assume that progress in the same direction would run on, and the patient grow worse and worse, if the condition continued to be left to itself. Whilst matters are thus proceeding it happens, say, that the existence of the disease becomes recognized, and, if the case be such that the sugar is susceptible of being removed from the urine by the exclusion of the carbohydrate principles from the food, and this exclusion be carried out, this alone will suffice, not only to check the downward progress occurring, but to bring back health and strength to the patient.

"The first consideration, therefore, in the treatment is to control by dietetic measures the passage of sugar through the system. The real point, however, to be aimed at, is to restore the assimilative power over the carbohydrate elements of food, and until this has been accomplished it cannot be said that a cure has been effected, but only that the disease is held in subjection, and prevented, as long as the condition can be main-

tained, from leading on to an unfavorable issue. What most conduces to this desired restoration of assimilative power is the maintenance of a normal state of the system by keeping it free from the passage of sugar through it, and in this way bringing a healthy condition of body to bear in helping to promote a removal of the faulty state.

"According to my own experience, opium and its derivatives, codeine and morphine, are the medicinal agents which, more than any others that I know of, assist in the actual cure of the disease, by which I mean a restoration of the assimilative power which has been impaired.

"The influence of these agents may be witnessed in cases where the sugar has been brought down by diet to a certain point, but is unsusceptible of entire removal from the system by dietetic treatment alone. The complete removal may then be sometimes observed to follow the subsequent administration of the drug, showing that the medicinal agent has acted in the direction of exerting a restraining influence over the abnormal production and elimination of sugar."

Correspondence.

[Special Correspondence.]

THE BERLIN INTERNATIONAL MEDICAL CONGRESS.

BERLIN, August 10, 1890.

MR. EDITOR:—If Sterne was right in thinking that things were "done better in France" in his day, the friendless and tongue-tied stranger and foreigner who arrived at Berlin, a new-comer to the great "medical roundup," would agree that the German principle that every traveller is to be looked upon as a child and in need of being led by the hand has its advantages.

We in America are fond of thinking that every able-bodied man can find his way anywhere, and is a fool if he wants a guide other than a sign-board, and it is a new sensation to be watched like a sheep whose natural inclination is to break from the lead,—in fact an Anglo-Saxon can not escape a slight spirit of rebellion if he is firmly though kindly prevented from making an exit where his entrance was; but his reason triumphs over his individualism, if he uses a slight amount of reflection. In short, nothing could be more excellent than the arrangement for registration and delivery of tickets, which is always an annoyance, and in a congress of 3,000 might be a matter of no little difficulty. And when the central organization attempts the banking business of supplying money for the delegates on letters of credit, and changes his foreign money for him, the practical American admits that he is the personal debtor to the members of the committee for their trouble-saving arrangements. He feels that he can anticipate from such excellent preparations at least a feast of reason, even if a flow of soul does not fall to his lot as a stranger.

The opening ceremonies were on the whole as dignified as could be desired, and the presence of a large number of uniforms and orders gave to the spectacle a brilliancy particularly pleasing to an American, accustomed at home to the undramatic garb of the visiting doctor, however distinguished, on such occasions.

Professor Virchow wears his years very lightly, and showed little age in his extremely long opening address, which glorified the city of Berlin for the amount of money spent on sanitary matters in a way which reminded the American of the Fourth of July address of his boyhood. The facts, however, undoubtedly deserve glorification; but the fervid heat of August does not make an audience of 3,000 sympathetic to a detailed statistical recital of the

number of million of marks expended. The welcome extended to Sir James Paget, if one can judge by the hearty enthusiasm of applause in an unusually undemonstrative audience, bespoke a tribute to a character which, in purity and rectitude as well as in ability, has made itself widely felt in a day when self-assertion has too often claimed undue prominence. The welcome of a hearty applause greeted the announcement that 500 delegates had arrived from the United States. The fact is certainly a noteworthy one, and to be explained on the theory that the American doctor is particularly eager for knowledge, or is prosperous, or is fond of travel, according to the patriotic optimism of the theorizer or his pessimism.

The congress drew delegates from China and Japan and from Russia, so that it may fairly claim to be international, probably more so than any previous congress.

The honors given to Lister of the opening scientific paper were fully deserved, but it can hardly be said that he was equal to the occasion,—an occasion, be it said, which might tax the oratorical ability of the greatest of speakers.

The disadvantages of so unwieldy a congress in numbers was quite apparent on the first day, as soon as the surgical section attempted to visit Bergmann's clinic; but although it was difficult to obtain much information as to the aseptic methods by actual observation owing to the crowd, a paper with aseptic details and rules carefully printed was distributed freely, and, it may be hoped, will be carefully read and copied in every surgical hospital in the world. The methods of antiseptic surgery formerly employed in the clinic have been followed by thorough aseptic methods. All cloths, towels, sheets, etc., which come in contact with the patient are thoroughly sterilized before operation by steam heat, and kept clean; in short, nothing touches the patient which is not perfectly clean. The dressings used are also sterilized, and the details of aseptic surgery are strictly carried out in all operations; but antiseptic preparations and washes are not used in simple operations on aseptic cases.

Bergmann, in appearance, fully justifies his position as leading German surgeon,—slightly above the average height, he is of a broadly-built figure, and, though of a darker complexion than is usually seen in North Germany, has that tendency to corpulence peculiarly national which betokens a plenty of attention to German living, and that mental content which comes with the honor of Geheimerath. To see Bergmann kiss Ollier on the cheek in token of professional brotherhood is intended to stir the enthusiasm of the surgeon, who is to believe that there is but one nation, and that is Science, which looks down on the petty brawls of cabinets,—all of which, however, would be more inspiring if one had not the feeling, true or otherwise, that the action of the Geheimerath and of the German committee were at the instance of the present ministry, and was something like the action of our politicians in behalf of the poor soldier, or the tariff after the National Republican Committee had thought the matter over.

Horsley is said fairly to have won honors in the congress by his perfect demonstration and his remarkable experiments.

Oppenheim reports a case of successful removal of a sarcoma of the brain three months ago, on a woman who a month ago gave birth to a healthy full-term child.

Although the Americans were numerous and were kindly received, it cannot be said that they won as great distinction as was granted their *confrères* from England or France. Dr. Billings certainly deserves to be placed in the front rank of distinguished men. But if few Americans of great distinction visited Berlin, the American representatives were numerous as well as observing and alert; and to few nations will the benefit of the congress be greater than to the United States, whose profession is particularly ready to adopt suggestions, and there were many.

The exhibition given under the auspices of the Congress

was well worth careful study, and full of objects of interest. The inevitable beef-essence exhibition was not absent; and the patent bath-tub, medical appliances, etc., were decidedly below the standard of ingenuity and workmanship which is often seen in the American Medical Association. But in extent, variety, good selection, etc., the exhibition left little to be desired. What at least may be called a surgical novelty was the exhibition of a number of cases by Gluck, who certainly deserves the palm for bold surgical experimentation on human subjects.

At the exhibition a skeleton was shown, with ivory joints inserted at the wrist, knee and hip, and in a number of the smaller joints, and also an ivory vertebra to replace the second dorsal vertebra. The skeleton attracted little attention, except as showing a surgical nightmare; but when it was known that Herr Gluck would show a certain number of living patients wearing ivory joints, curiosity and interest were naturally excited, and the little operating room in Ziegel Strasse, which is attached to Gluck's Polyclinic, was crowded by many distinguished surgeons of different nationalities, to see this exhibition of surgical fireworks. It seems incredible; but the truth remains that Gluck showed a patient on whom, nine weeks before, he had not only excised a knee for tubercular disease, but inserted an ivory joint, driving the free ends of the articulated pieces of ivory three or four inches into the medulla of the shafts of the femur and tibia respectively. Motion at the knee was free and painless, but the patient had not been allowed to walk. A few other cases of excision of the wrist, the shaft of the humerus, and the knee were also shown, on whom the same method had been employed; also a piece of ivory that had been worn for some time in the humerus of a dog.

Gluck's idea evidently is, that if small ivory plugs are absorbed, large ones will not be; and if these are, he promises to use aluminum. He seems to have overlooked, so far, the future necessity of oiling the joints; but that, of course, may be regarded as a trifling detail, although the whispered suggestion of this fact to an open-mouthed, horrified English surgeon who was inspecting the case, nearly caused apoplexy.

Criticism is naturally silent before surgery of this sort. One simply bows to the boldness of the experimenter who is not bound by tradition or fear of suits for malpractice, which must be few in Berlin.

Time and space prevent any allusion to the hospitality in Berlin; but one will venture to hint that the mammoth *Kneipe* at the *Rathaus*, offered by the city of Berlin in the harmless guise of a reception, will be remembered by the visiting physicians when Virchow, Koch, Bergmann and other great men are long forgotten. Certainly, our junketing aldermen and councilmen would admit that, in their palmiest and most riotous days, they are but pygmies in comparison with the city government of Berlin. A fervid imagination could not equal the reality. Certainly, in this respect, "they do these things better in Germany."

CRANIECTOMY FOR MICROCEPHALIC CRETINISM.

WAVE CREST, N. Y., August 28, 1890.

MR. EDITOR: — Another "ectomy" has just been added to the still broadening stream of new procedures in legitimate surgery. Strange to say, in this instance, it is not a novel abdominal excision that is heralded to mark the new era. All the eggs in that basket have already been hatched — some of them pretty poor eggs, too.

We all know, in these days of our waning century, that a mere enumeration of the contents of the artful belly, with the obligatory "ectomy" hitched on regardless of etymological propriety, will suffice as an index of operations which the abdominal surgeon or, for short, "subdiaphragmatic chirurgeon," is ready to perform at all hours of the day or night, while you wait. With rare cunning, the envious Frenchman, perceiving that the Teuton had exhausted the

resources of abdominal "ectomies" and "ectotomies," has suddenly shifted the scenes. And behold, ye men of the gizzard, the head (which in man is sometimes placed above the stomach) will now come in for a tardy share of our all-popular "ectomies." The Gallic bugle already sounds, in unmistakable notes, the latest triumph of her surgery. Says the *Union Médicale* of recent date, "French surgery, which has been accused of being behind that of other nations, from time to time, still demonstrates its leadership."

In proof of this assertion, the journal proudly says (see the communication just made to the Paris Academy by Professor Lannelongue, who has successfully craniecomized two microcephalic French idiots), "Cranieotomy marks immense progress in the treatment of an affection hitherto considered as incurable. Until now," continues the *Union*, "we had to content ourselves with putting the unfortunate microcephalic idiots in asylums. But M. Lannelongue has thought that we could do better. The mental condition of microcephali has been justly attributed to incomplete encephalic expansion, due to premature closure of the cranial sutures. To remedy this evil, the bony box enclosing the brain must be made larger, in order to permit cerebral expansion."

Putting into practice this theoretically perfect reasoning, an idiotic child was selected, an incision made over one parietal bone, a slice of the latter removed (five inches long by one and a half inches wide), the cutaneous wound closed, an antiseptic dressing without drainage applied, — and the thing was done. Unlike most first trials, the operation under discussion was entirely successful, even in that minor matter of modern cuttery, the preservation of previous vitality on the part of the patient. The particular child in question not only lived, but it soon showed signs of unmistakable intelligence, such as biting people's thumbs, and other playful pranks that only doting parents fully fancy.

Encouraged by his success, Dr. Lannelongue craniecomized a second idiot. But we are told that sufficient time has not yet elapsed since the performance of the operation to accurately gauge this baby's mental caliber. But his condition is, at least, promising; and he will probably live to put many an uncraniecomized infant to shame by posing as a professional prodigy when his *confrères* still babble in that orthodox "silliness supreme" so characteristic of merely natural babies.

The parting injunction of the *Union Médicale* will please be heeded: "When, in future, admirers of foreign surgery again make unfair comparisons, we beg them not to omit giving us [the French] credit for cranieotomy." It is to avoid the possibility of such rank injustice that this early notice of the operation is given to your readers.

EDMUND CHARLES WENDT, M.D.

SOCIETY NOTICE.

AMERICAN ORTHOPEDIC ASSOCIATION. — The Fourth Annual Meeting will be held at the College of Physicians, Thirteenth and Locust Streets, Philadelphia, September 16, 17 and 18, 1890.

Tuesday, September 16.

Morning Session. Address by the President. Spinal Distortions and their Treatment by the Straightened Leather Jacket, Dr. Bernard Bartow, Buffalo. Treatment of Deformities of Spastic Paralysis, Dr. E. H. Bradford, Boston. Tenotomy for Relief of Deformity in Spastic Paralysis, Dr. Arthur J. Gillette, St. Paul. Amputation as an Orthopedic Measure, Dr. Ap. Morgan Vance, Louisville.

At 1 P. M. Members of the Association are invited to inspect the Presbyterian Hospital, Thirty-ninth and Market Streets; take Walnut or Market Street cars to Thirty-ninth Street. After which lunch will be served.

Afternoon Session, in the amphitheatre of the hospital, or at the Presbyterian Hospital. A Ready Method of Counter Traction at the Knee, Dr. Henry L. Taylor, New York. Treatment of Infantile Club-Foot, Preliminary Operation, Dr. F. H. Miller, New York (by invitation). Paralytic Club-Foot, Dr. W. E. Townsend, New York. Ten Years' Experience in the Management of Knee-Joint Disease, Dr. V. P. Gibney, New York. The Inefficiency of Mechanical Treatment in Spasmodic Wry Neck, with a report of three cases, Dr. George W. Ryan, Cincinnati. Sacro-Iliac Disease, Dr. Benj. Lee, Philadelphia. Instantaneous Photograph, illustrating the gait of a child from whom both hips had been removed, Dr. H. M. Sherman, San Francisco.

Wednesday, September 17.

This day will be devoted to the subject of *Rotary Lateral Curvature of the Spine*. The following papers will be read, after which there will be a general discussion of the subject.

Morning Session. — The Normal and Abnormal Elements in the Causation of Idiopathic Curvature, Dr. Benj. Lee. The Muscular Element in the Etiology, Dr. Chas. L. Scudder. Etiology, Dr. R. W. Lovett. Mechanism of Rotation, Dr. A. B. Judson. The Mechanical Theory, Dr. O. H. Allis (by invitation). Causes, Dr. M. T. Biessel (by invitation).

At 1 P. M., after adjournment, the Association is invited to inspect the Orthopedic Hospital, Seventeenth and Summer Streets, after which lunch will be served.

Afternoon Session. Pathogeny, Dr. Newton M. Shaffer. Treatment Especially Applicable to Poor and Dispropitious Patients, Dr. V. P. Gibney. Treatment, Dr. E. H. Bradford. Treatment, Dr. B. E. McKenzie. Treatment, Dr. Henry Ling Taylor.

Thursday, September 18.

Morning Session. The Significance and Value of Involuntary Muscle Protection in the Lives of the First Apparient Stage of Hip Disease, Dr. Newton M. Shaffer, New York. Treatment of Hip Disease, Dr. B. E. McKenzie, Toronto. A Report of Sixty-two Cases of Hip Disease observed in the practice of Hugh Owen Thomas, Dr. John Ridlon, New York. Diseases of the Eye associated with Spinal Caries, Dr. James K. Young, Phila-

delphia (by invitation). Posterior Rachitic Curvature of the Spine, Dr. Samuel Ketch, New York. From the Pennsylvania Hospital, Eighth and Spruce Streets, after which lunch will be served, by the invitation of Benjamin Lee, M.D., at 1.30 P. M., at his residence, 1532 Pine Street, when an opportunity will be offered to inspect his Orthopedic Gymnasium.

Afternoon Session. Lateral Deviation of the Spinal Column in Pott's Disease, Dr. R. W. Lovett, Boston. Relief of Paraparesis, Dr. A. J. Steele, St. Louis. Prognosis of Pressure Paralysis, Dr. T. Halstead Myers, New York. Do Orthopedic Surgeries Operate as Frequently as they Should? Dr. J. E. Moore, Minneapolis. Joint Diseases, Dr. John Ridlon, New York. Papers (titles not sent), by Drs. T. G. Morton, Roswell Park, and Associates.

Members are invited to visit the Presbyterian Hospital, Thirty-ninth and Market Streets; the Orthopedic Hospital, Seventeenth and Summer Streets; University Hospital, Thirty-fourth and Spruce Streets; Children's Hospital, Twenty-second, below Walnut Street; Pennsylvania Hospital, Eighth and Spruce Streets; White Cripple's Home, Forty-fourth Street and Baltimore Ave., and the Colored Cripple's Home, Forty-third and Wallace Streets.

GEO. W. RYAN, M.D., Recording Secretary and Treasurer,
114 West Ninth Street, Cincinnati.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 23, 1890.

Deaths reported 2,260; under five years of age 1,068; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 616, consumption 242, acute lung diseases 130, diarrhoeal diseases 409, diphtheria and croup 60, typhoid fever 57, whooping-cough 37, malarial fever 20, scarlet fever 16, cerebro-spinal meningitis 10, erysipelas and pyrexia 10, fever 10.

From whooping-cough, New York 16, Philadelphia 9, Baltimore 4, Salem and Waltham 2 each, Washington, Lowell, Lawrence and Chelsea 1 each. From malarial fevers, New York 7, Philadelphia and Baltimore 3 each, Charleston 2, Nashville and Fall River 1 each. From scarlet fever, New York 4, Philadelphia 3, Worcester 2, St. Louis, Malden and Pittsfield 1 each.

* Twenty-one deaths by railroad accident; one, under five years of age, not included in the number returned as under five.

From cerebro-spinal meningitis, Lynn 4, New York 3, St. Louis, Baltimore, Boston and Washington 1 each. From puerperal fever, Boston 1. From erysipelas, Boston 1.

In the twenty-eight great towns of England and Wales with estimated populations of 9715,359, for the week ending August 9th, the death-rate was 19.2. Deaths reported 3,078: infants under one year 1,230, diarrhoea 40, measles 152, whooping-cough 60, scarlet fever 50, diphtheria 34, fever 25.

The death-rates ranged from 14.3 in Blackburn to 28.3 in Preston, Birmingham 20.1, Bradford 17.6, Hull 14.4, Leeds 19.5, Leicester 19.3, Liverpool 21.6, London 18.8, Nottingham 14.5, Sheffield 24.4, Sunderland 17.6.

In Edinburgh 17.5, Glasgow 19.4, Dublin 18.6.

The meteorological record for the week ending Aug. 23, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.			Relative Humidity.		Direction of Wind.	Velocity of Wind.	State of Weather.*	Rainfall.
		Daily Mean.	Maximum.	Minimum.	8.00 A. M.	8.00 P. M.				
Saturday, Aug. 23, 1890.	Daily Mean.	68.0	85.0	60.0	83	82	S.W.	S.W.	8.00 A. M.	
Sunday... 17	68.11	86.0	85.0	60.0	83	82	S.E.	4	8.00 P. M.	O.

Mean for Week.										0.16

*O, cloudy; C, clear; F, fair; G, fog; H, hazy; S, smoky; R, rain; T, threatening; N, snow. + Indicates trace of rainfall.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 30, 1890.

A. A. HOCHLING, medical inspector. In addition to present duties, ordered as President of Medical Examining Board at Philadelphia, convened by Department's order June 9, 1890.

R. M. KENNEDY, assistant surgeon. In addition to present duty, ordered as member of the above Board.

F. N. OGDEN, passed assistant surgeon. In addition to present duty, ordered as member of the above Board.

WALTER A. McCLELLAN, surgeon. Granted a month's leave of absence from September 1st.

EDWARD KERSHNER, surgeon. Granted two weeks leave of absence from September 1, 1890.

AN ARMY MEDICAL BOARD

Will be in session in New York City, N. Y., during October, 1890, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before October 1, 1890, for the necessary invitation, stating their date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of services in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a Regular Medical College, as evidence of which his Diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D. C.

J. H. BAXTER, Surgeon General U. S. Army.

TWO CASES OF LAPAROTOMY FOR TUBERCULAR PERITONITIS.¹

BY LEONARD WHEELER, M.D., OF WORCESTER.

CASE I. C. K. was seen first in consultation with Drs. Homer Gage, of Worcester, and Gifford, of Leicester. We agreed in the diagnosis of tubercular peritonitis, and advised admission to the City Hospital for laparotomy.

August 6th, 1889, he was admitted to the service of Dr. Rich, by whose kind consent I include this case with my own. He was seventeen years old, single, operative. Family history negative. Habits alcoholic. Had always been perfectly well up to three weeks before entrance, when he was seized with pain in the bowels, which gradually grew worse. He kept about his work for several days, and was then obliged to go to bed. Abdomen had increased in size until at time of entrance it was very full and tense. Appetite was gone; there had been some vomiting. Bowels inclined to constipation. The abdomen was everywhere tympanic, there was no ascitic wave, it was but slightly tender, there were no hard masses. Temperature 100°; pulse 100; urine and chest examination negative.

August 8th. Etherized; laparotomy by Dr. Rich; median incision below umbilicus, four inches in length. Upon opening the peritoneum, clear straw-colored ascitic fluid escaped to the amount of a few pints. The peritoneum was studded with small nodules. Light adhesions were general. These were not extensively disturbed, but the cavity washed out as well as possible with a weak bichloride solution, 1-5,000, followed by a 1-16 boroglyceride solution. A large rubber drainage-tube was left in. The peritoneum was closed with catgut, and the remaining parietes with silk sutures. Dry iodoform and bichloride gauze dressing.

The tube was removed the next day; sutures taken out at the end of a week. Union was complete, except the drainage opening. One stitch had suppurred, and through this opening there was some drainage, the fluid containing now flakes of lymph and becoming darker colored.

As to the condition of the patient, it seemed at first a little improved, but in a few days he began to lose ground steadily again. The abdomen refilled. At the end of a month it was again opened. There were firm adhesions all about, and it was impossible to get far in the attempt to cleanse the cavity. The course of the disease was not much modified, either for better or worse, by the surgical treatment. The patient gradually failed, and died six weeks after the first, and two weeks after the second operation. No autopsy was allowed.

CASE II. E. C. entered the Memorial Hospital in my service January 30, 1890. I had seen her in consultation a few days before, and supposed she had an ovarian tumor. She was a thin, pale, worn-looking woman of twenty-nine. Had been seven years married; two children, six and three years old. Family history, negative. She stated that one and a half years ago she had been in poor health for some months; but I failed to learn then, as I did afterwards

from a former medical attendant, that she was at that time supposed to be phthisical. A month before entrance she had first noticed a tenderness of abdomen and a pain about pelvis. Her attention thus attracted, she observed a swelling of abdomen. Has lost much flesh; has had some nausea; frequently required opiates for abdominal pain. At my first examination the abdomen was full, not tense, somewhat tender, and I could feel bimanually an elastic, nearly median tumor, apparently with pelvic connections, in size something less than a child's head. At a later examination I could not make it out so plainly, and the percussion was a little at variance with the idea I had formed. Still the ovarian idea was not dislodged from my mind. There was a small amount of ascites. The uterus could be felt anteriorly, and measured two and a half inches. Examination of urine gave a slight trace of albumen; otherwise negative.

February 14th. Patient was lightly etherized, and the abdomen opened by median incision below umbilicus. The parietes were very unusually vascular, one artery spurting fully a foot. The tissues were very friable, so that bits would crush quite off in the compression forceps. No tissue structures, muscle, linea alba or omentum were recognizable. Entrance to the peritoneal cavity was indicated by a gush of ascitic fluid, —greatly to my relief, for I was much afraid of opening intestines. Putting in my finger, I seemed to feel a tumor everywhere adherent to the parietes. Tearing adhesions when I could —some were too strong—I followed the tumor into the pelvis, behind the uterus, which was quite smooth and free from adhesions. At a short distance from the uterus, both broad ligaments disappeared into the mass. An enlarged incision showed the tumor to consist chiefly of intestines matted together. There were no sulci between the folds, but an even translucent surface presented, through which the coils of intestine could be faintly seen. The amount of ascitic fluid escaping as adhesions were torn, was a pint or two, of turbid straw color, with flakes of fibrin. There was considerable hemorrhage from adhesions. There was nothing to do; the adventitious tissue surrounded the intestines like a mould, and it was impossible to free them. The bleeding was stopped with hot water and the wound closed. A rubber drainage-tube was left in.

On the next day the tube was replaced by an iodoform ribbon, though there was no profuse discharge. Sutures removed in ten days; union complete except at point of drainage. Three weeks after operation the record is: "Since operation patient has had less pain, and taken more nourishment, but her general condition has not been changed. The temperature has kept along about as before, ranging from normal to 101 $\frac{1}{2}$ °—except for a few days after operation, when it rose to 102 $\frac{1}{2}$ °. It was found subnormal only once. Pulse before operation, 110-125; after, 100-110. The bowel movements became natural after the operation, which they had not been for a long time before."

March 8th, she wanted to go home, and was discharged. The drainage opening never closed, though there was never any great discharge. This fistula became fecal after she went home, and she died of exhaustion about five months after the operation.

Here are two cases of tubercular peritonitis in which abdominal section was done with no good effect.

¹ Read before the Massachusetts Medical Society, June 10, 1890, and recommended for publication by the Society.

Neither do I think the fatal termination was materially hastened thereby. Where was the fault in these cases? I shall inquire whether the operation of abdominal section for tubercular peritonitis is ever justifiable, and if so, under what circumstances, and in what way? First, a word as to diagnosis. The diagnosis of tubercular peritonitis is frequently difficult, and thus far has proved often impossible. Under the encouragement of a chance for cure, the diagnosis will be more frequently made, and fewer cases will pass for typhoid fever and ovarian tumor. In a table of seventy-one operated cases of tubercular peritonitis given by Maurange² in a thesis last year on the subject of "Surgical interference in tubercular peritonitis," — of these seventy-one cases the diagnosis was made before operation in fourteen, or one-fifth; while in forty, or well above one-half, the preliminary diagnosis was ovarian tumor. As the question is more closely studied, more indubitable diagnosis will be required, especially to discriminate from chronic peritonitis without tubercle, in regard to which pathologists are at variance — some thinking it common, others rare. Diligent search ought to be made in each case for the tubercle bacillus, not in the fluids, — for a negative result there is the rule, — but in the tissues themselves, or perhaps in scrapings from the surfaces of the cavity. The proposal of inoculation of animals is made, but so many of these experiments have been negative, that not much confidence is put in this method. The question whether abdominal section is ever justifiable is, I think, pretty well settled, and especially so in this locality by the work of Homans, Cabot, Elliot and Bradford.

However, text-books up to the most recent editions agree in regarding tubercular peritonitis as a hopeless disease. A newest text-book, however — "Taylor's Hand Book of the Practice of Medicine" — has this: "A considerable number of cases have now been successfully treated by opening the abdomen, washing out and sponging the surfaces of the peritoneum and inserting a drainage tube."

Tait, in the Edinburgh *Medical Journal*, November, 1889, says in his usual broadcast way: "That a therapeutic change is effected in the peritoneum itself by the mere opening of the cavity is now universally recognized in the treatment of what we call tubercular peritonitis by abdominal section. I have now had a large experience on this point, and can say positively that we can cure, permanently and speedily, cases that have gone even so far as suppuration by opening and cleansing, but in bad cases the cleansing is in all probability not complete, no matter how much care and time are spent on it, and in the non-purulent cases I very often do no cleansing at all, but merely empty out the serum and put in a drainage pipe. Yet the great majority of these cases are cured by these simple means." Somewhere else he says eighty per cent. are cured. I have myself no doubt that this strong statement will have to be modified.

Formerly, if one maintained the curability of tubercular peritonitis one's diagnosis was questioned. But that position of doubt cannot be held. The results of autopsies in general are enough to refute it. The record of any pathologist of large experience would furnish cases of latent peritonitis in persons who had died from other causes.

² Maurange. De l'intervention chirurgicale dans le peritonite tuberculeuse. Etude critique et statistique. Paris, 1889.

Pribram³ of Prague, writing in 1887, and dealing with a total of 3,500 autopsies, found 165 in which tubercular peritonitis existed. Most of them died, not of the peritoneal disease, but of pericarditis, pleurisy, meningitis or tuberculosis of lungs. The peritonitis was a secondary matter, and often retrograde. It was only in a few of the cases that the peritonitis was the cause of death.

Osler⁴ details several cases, when, after death from pulmonary tuberculosis, the traces of peritoneal tubercles cured, or in process of cure, were found. Moreover, Pribram found no cases of chronic exudative peritonitis among the 3,500 autopsies, which is incompatible with the idea that this form of disease — the non-tubercular sort — is so common as to account for all the cases which are diagnosed tubercular peritonitis, and which get well under medical treatment. Other observers, to be sure — Spaeth, Welch, Prochnowick — hold a contrary view; that there is a form of simple chronic peritonitis with quite similar fibroid nodules, but in fact not tubercular. Such a difference in view must at least indicate a considerable rarity of the simple form.

If any further proof were necessary of the curability or recoverability of tubercular peritonitis it is most indubitably furnished by the experience of modern surgery. Since abdominal section has become common, numerous cases have occurred in which the retrograde process has been observed either in the living body or in the body dead from other causes after longer or shorter interval. Pribam gives the case of a woman discharged from hospital relatively well of an illness diagnosed tubercular peritonitis. One and a half years later Breisky did an ovariotomy on the same patient. Microscopic examination of the peritoneum at the time of operation showed the remains of tubercular disease, and bacilli were even then present.

Ceccherelli⁵ operated on a boy of eleven in whom ascites was the only physical sign. The peritoneum was covered with tubercles. The ascites had returned in a month, so that laparotomy was again done. The number of tubercles had greatly diminished, and those remaining were found covered closely with recently-formed connective tissue, thus showing the method of repair in these cases. — Osler gives a very interesting case in point, which I will not detail. He says of it: "Surgically the operation was a success, as the symptoms were relieved and she left the hospital looking and feeling well. Then death following a short illness, gave an opportunity of studying the condition of the peritoneum four months after. The tubercles were found undergoing fibroid change, but still retaining their characteristic structure and still rich in bacilli."

In a list of forty-one cases of abdominal section for tubercular peritonitis reported by Kümmel⁶ in 1887, are two where the miliary tubercles were seen on the peritoneum at the operation, and were not to be found at all at the autopsy after death a few months later. Ahlfeld⁷ reports a similar case one and a half years after operation. In addition to these proofs, furnished by autopsy and microscopical examination of retrograde processes set up after operation, we have the

⁷ Ahlfeld: Quoted by Osler.

clinical history of many cases which have improved in health, or, so far as we can say, have got well, after laparotomy. Building upon this, men have begun within the last few years to operate for the tubercular disease alone, when it could be diagnosed, and with what success I will endeavor briefly to indicate. It is not essential to my purpose to separate the cases in which the diagnosis was previously made.

As to the proportion of operative cases cured it is a question which it is not possible to answer in any but a vague, indicative way. It is common in cases of tubercular peritonitis — even symptomatic in their clinical history — that there should occur periods of quiescence or obsolescence — the disease advances with remissions and exacerbations. In an analysis by Vierordt⁸ of twenty-four *clinical* unoperated cases, there was one finally fatal after a remission of three years, and this is only an example of a class of cases observed by him and others. This fact keeps the cures for a long time doubtful.

It is of little importance to know the number of cases in which the operation is *surgically* successful. There is not much danger in the operation, less, it would seem, than in a laparotomy where the peritoneum is healthy. The thing is to know when permanent benefit is to be hoped for. There is next to no danger of the operation itself being fatal, though, to be sure, some such have been reported. Maurange tabulates 71 cases of abdominal section for tubercular peritonitis. Osler, in a recent article in the Johns Hopkins Hospital reports, adds 26, and I have gathered 29 others. Making in all 126 cases.

Assuming that survival one year after operation entitles a case to rank as successful, I find among 126 cases 37 such, or 30 per cent. There is nothing accurate about this, for many of the cases in my table were reported within a year of the operation, so could not possibly come into this category; still it gives an idea. It shows that the number of cases surviving twelve months must, at all events, be more than 30 per cent. Most of these surviving cases were reported "well" at the end of the year, but I am unable to make any satisfactory estimate of the number of complete cures in this list.

Of the 55 cases which I have selected, outside of Maurange's table, 36 were living, and most of them called well, at various intervals from one month to four years, that is 66%.

Again, of the 55, 8 were living and explicitly *well* at the end of a year. This would make a rate of cure nearly 15%. This is certainly below the true proportion of 12 month cures, since a large number of this series of 55 were reported within less than a year of the operation.

These figures, — 30% of 126 cases surviving at the end of a year, and 15% of 55 cases *well*, apparently cured, at the end of a year, — are certainly encouraging, in view of the quite hopeless fate formerly apportioned to the victims of this disease. These facts show no such victory as Tait celebrates when he claims 80% of cures, but still a victory.

The calm facts are that certain cases of tubercular peritonitis are open to surgical cure. Although no general cure has been discovered, a step in advance has been made.

Now as to the kind of case which promises good

⁸ Vierordt: *Über die Tuberkulose der Serösen Hämme*, Zeitschr. f. Klin. Med., B. 13, H. 2.

results after operation. Not all cases of tubercular peritonitis are to be operated on, by any means. A certain number get completely well without operation, and another number is outside the possibility of help. A certain group of cases are unhesitatingly to be operated upon, another group are to be unhesitatingly left alone, while in others the question must be decided on individual merits. It is impossible to settle the question by tables of symptoms, but I will enumerate a few of the indications and contra-indications, prefacing that the general condition of the patient will perhaps settle the question of operation or no operation, as often as anything.

First. Indicating operation:

- (1) Abundant ascites.
- (2) Absence or small amount of solid masses.
- (3) Disease primary in the peritoneum, though the mere presence of tuberculosis elsewhere does not forbid operation. Some cases have apparently recovered entirely, when there was slight co-existing disease of the lung, both peritoneum and lung becoming healthy.
- (4) Encysted disease, that is, serous or purulent pockets.
- (5) Intestinal obstruction.

In the last two, operation is imperative.

On the other hand, contra-indicating operation:

- (1) Absence of ascites.
- (2) Abundant masses or strands.
- (3) Secondary to advanced general tuberculosis.
- (4) Intestinal ulcers.

The last two forbid operation.

As to method of operating. The abdomen should be cleaned out as well as possible, by flushing with hot water and sponging; separating meanwhile any adhesions which can be broken without injury to the viscera. No antiseptic and no drain, unless for some special reason, as, for instance, hemorrhage.

Tapping should not be practised. There is danger of doing harm, and it cannot do so much good as laparotomy.

Returning to my two cases, I should still advise operation in the first case, that of the man, with ascites and light adhesions, though I think it ranks with doubtful cases and perhaps should be excluded on account of its acute character, its rapid and uninterrupted course. It would certainly have been better to break up adhesions everywhere, so laying open any loculi there may have been, and making a more thorough peritoneal toilet.

The second case was operated under mistaken diagnosis. Had the diagnosis of tubercular peritonitis been made before operation, the absence of ascites, the presence of so much solid mass, and its probably secondary character, would have contra-indicated operation.

In neither case would I put in a drainage-tube, for it does no good, unless, of course, there is some special indication, and the tube track is very likely to remain fistulous, or even become fecal, as in my second case, by ulceration through the intestinal wall from the outside.

— A decimal point is a small point for a human life to hang upon. It was a point so indistinct in a New York physician's prescription that the druggist put up 75 grammes of aconite, instead of 7.5 grammes as intended. The mother of a sick baby, for whom the medicine was given, tested it by tasting from the bottle, and was killed.

A FORM OF POLYNEURITIS, PROBABLY ANALOGOUS TO OR IDENTICAL WITH BERIBERI, OCCURRING IN SEAFARING MEN IN NORTHERN LATITUDES.¹

BY JAMES J. PUTNAM, M.D., OF BOSTON.

On the 21st of last October, a man, thirty-nine years old, the mate of a fishing-vessel that had just arrived from the Grand Banks, was referred to me by Dr. M. A. Morris, of Charlestown, and gave the following account of his condition: He was suffering from weakness in both arms and legs to such an extent that he could walk only with difficulty. His legs felt numb and prickly, and he had observed an actual loss of sensibility of the skin. This feeling of numbness extended up the legs and thighs and over the lower part of abdomen to the umbilicus. The arms were in a similar condition, but to a less degree. No affection of the face or eyes had been noticed. There was no pain anywhere, and no affection of the sphincters of the bladder or rectum. He said the legs were swelled, but not so much so as they had been a short time before, and that the calves and the inner surface of the thighs felt sore and lame. He reported that he had been well up to two weeks previously. The first symptom noticed was pain on the inner surface of the thighs, on the 7th of October. The next day he felt sick, and the swelling of the legs and thighs showed itself. He kept in his bunk for several days, feeling weak and depressed, with a steady diminution of strength in legs and feet. Since then he had improved only slightly. He had had no fever so far as he knew.

On examination, the patient was found to be pale, with a yellowish cast to the skin of the face. His gait was waddling; the legs were used like stumps, and the feet brought down flat on the ground, as if simply hinged at the ankle. He had considerable difficulty in getting his coat off and on. In going down stairs he was obliged to turn sideways and to bring both feet down upon each step. There was slight toe-drop; and marked swaying of the body when the patient stood with the eyes shut. There was no inco-ordination in the arms or hands. The grasp by the hand was feeble on both sides, more so on the left. Extension of the fingers and carpus was imperfect on both sides. The sensibility of the hand to touch was so nearly perfect that the patient could feel the lightest contact with my finger everywhere. The sensibility to contact in the feet and legs was but little below the average, but the character of sensation imparted was not quite normal. The prick of a pin was promptly and distinctly felt, and, indeed, the patient's answers suggested some degree of hyperesthesia. A very light touch was also felt over the abdomen below the umbilicus, but as compared with the area above the umbilicus, the sensibility of the affected part was slightly impaired, or, at least, the contact gave rise to a feeling of a different kind in the two parts. A piece of metal of the temperature of the room was distinctly felt as cold wherever tested. The knee-jerk was absent on both sides, even during "reinforcement."

The calves of the legs were large and tender on both sides, distinctly more so than normal, by the patient's account, and there was pitting on pressure along the shins. The muscles over the inner surface of the thighs were also tender to deep pressure, and, to a slight degree, the muscular masses of the arms. No

enlargement of the spleen could be made out. Inquiry into the patient's previous history showed that he had been in all respects a temperate man. The pulse was 78, full and strong; temperature, 99° F. in the mouth.

To revert to the surroundings of the patient before the attack came on, it appeared that for nearly six months before his sickness he had been on a fishing vessel off the Grand Banks. The vessel had been very insufficiently provisioned, and the captain had insisted on protracting the trip, so that for some time the crew had had little else to eat except molasses, fried pork, and pancakes, and the water had been foul. Nine or ten other men beside the patient had been affected like himself, and most of them more severely. The first one was attacked two months before he was, namely, in August. Their legs were badly swelled, so that the pitting on pressure was frequently noticed. I learned further that some of these men had been treated at the Marine Hospital, and I was shortly afterward enabled through the kindness of the surgeon in charge, Dr. Fairfax Irwin, to learn something of their history and to examine one or two that remained. Dr. Irwin reported to me that on account of the oedema, the malnutrition, and in one or two more of the cases, the typical purpuric condition, he had made the diagnosis of scurvy, and it certainly seems highly probable that this affection accounted for a part of the symptoms.

Of the two patients remaining in the hospital, one was a typical example of multiple neuritis, presenting well marked wrist-drop and toe-drop, impairment of sensibility of the hands and feet, and more or less tenderness on deep pressure into the muscular masses of the arms and legs. He had been improving and soon afterward left the hospital.

Some months after these cases were brought to my notice a patient presented himself at the Massachusetts General Hospital, presenting the symptoms of multiple neuritis in even a more severe form than either of the cases already described, and bringing a note from his physician, Dr. Stone, who asked for a diagnosis, and said that he had seen several other cases of the kind. He gave the following history: Was a seaman, twenty-one years old, single, in good circumstances, and with absolutely no history of constitutional disease. He had been well up to the 1st of July, 1889. At that time he was in a fishing vessel off Block Island, near Newport, R. I., having left his home in Wellfleet early in June. The vessel was well provisioned. The first symptom consisted in a sense of numbness in the feet, which began at the toes and spread rapidly upward, but never reached more than midway up the thigh. Soon afterward the fingers also began to be numb, and the sensation extended in the same manner. At the time of the illness he was feeling as strong and healthy as ever in his life. The weakness of the arms and legs began almost at the same time with the numbness.

Soon after these symptoms appeared, the legs, as well as the lower half of the thighs, began to swell, and became highly edematous, pitting deeply on pressure. At the same time he began to have severe pain, mainly along the shin, accompanied by marked soreness on pressure. It is possible that this pain was due to the swelling, since the feet were not painful. There was no pain in the arms.

On the 26th of August, the patient began to suffer from dysentery of severe character, which lasted for two weeks and was followed by a severe diarrhoea, which continued for three months. He re-

¹ Read at the Annual Meeting of the Neurological Association, Philadelphia, June, 1890.

mained in bed all the time, having a very large number of movements daily, and, indeed, his legs became so weak that when he tried to stand he found it impossible to do so.

During a great part of his illness he was on shore, having left the ship after having been sick for a week or two. During the height of his illness he had several attacks of unconsciousness, lasting for an hour or so, accompanied by high fever, which was thought to be of malarial origin. For two or three weeks, just after the dysenteric attack, he was unable to control the sphincter of the bladder. At the time I saw him, he had improved considerably, both as regards the paralysis, which had been so great that all motion of the toes and feet was abolished, and the muscular wasting, which had been very marked.

The patient reported further that all the men aboard the ship, eight in number, were affected like himself to a greater or less degree, except that only one had the dysenteric symptoms. The paralysis was about equally great with them all, but did not in most cases last so long as with him. The other member of the crew who had dysentery, was attacked with it at about the same time with himself, and afterwards died.

The physical examination of the patient showed his condition to be characteristic of the so-called multiple neuritis, if not, indeed, that and something more. No motion was absolutely impossible, but a high degree of toe-drop was present, and the extensors of the carpus and fingers were much affected. He walked slowly, and only with the aid of a cane.

Examination of the sensibility showed that the sense of contact on the foot was slightly blunted to a little above the ankle. He was a good deal at a loss to localize the sensation, mistaking the sole of the foot for the dorsum, etc. The outer side and back of the foot seemed to be more affected than the sole. There was considerable delay in conduction. A piece of metal of the temperature of the room was sharply felt, even on the great toe. His sense of position seemed slightly impaired, so that he had difficulty in standing with the eyes closed, and he failed to state correctly the position of the toes. The foot felt cold to the touch. There was no static ataxia of the hand, and the sense of contact was apparently normal for the tips of the fingers. Two points were distinguished at about one millimetre. The electrical reactions for the muscles of the legs were much diminished.²

In October, 1881, Dr. F. C. Shattuck reported in the *Boston Medical and Surgical Journal* a series of cases evidently of the same character with those to which I have referred, and occurred under precisely similar conditions.

The patients were fifteen in number, and embraced all but four of the officers and crew of a fishing vessel, the *Nellie Swift*, that sailed from Provincetown for the Grand Banks on June 5, 1880. The first patient fell sick on August 1st, complaining of soreness in the calves of the legs and a dead feeling in the ankles, which was soon followed by swelling in those parts. The subsequent symptoms in this and the other cases consisted of extensive and severe anasarca, pain and

numbness. One of the patients died, having presented the above symptoms and, in addition, dyspnea with effusion in the chest. The urine had been scanty and high-colored, free from albumen, but containing a few granular casts. An account of the autopsy was sent to Dr. Shattuck by Dr. J. M. Crocker, of Provincetown, under whose care the patient had been. Serum had been found in the pleura, pericardial and peritoneal cavities. The heart was flabby, but otherwise normal. The kidneys were normal in appearance and size. The spleen was unusually small. Dr. Crocker further reported that none of the cases had, so far as he knew, presented hemorrhages, or other symptoms of scurvy, beyond edema of the ankles; and, further, that the drinking-water which was used on the ship was thick andropy.

As has been stated, the vessel was off the Grand Banks when the sickness broke out. During the previous winter, however, it had been engaged in the fruit trade in the West Indies, visiting Nassau among other places. The provisioning of the vessel had been practically the same as that of other vessels in the same trade. In a letter written a few months later, Dr. Shattuck also referred to the epidemic which broke out on a Brazilian man-of-war, said to have been improperly provisioned and in an unhygienic condition. Leaving Brazil, the ship sailed for Europe, touched at points in the Spanish Peninsula, and passed through the Suez Canal to Aden, where the disease, which was manifestly of the same character with that of the cases already reported, first broke out. The cases were treated in the Marine Hospital in San Francisco, and an account of them was published in the hospital reports. Dr. Shattuck concluded that the cases must be of the nature of beri-beri, and quotes Dr. Roosevelt as having described a series of cases which occurred on the *Henry S. Sanford*, which sailed from Hong Kong for New York, July 20, 1886. Of a crew of eighteen, twelve were attacked, and several cases were fatal. The outbreak of these epidemics on the last two vessels named is perhaps remarkable from the fact that it occurred so long after the vessels had left the southern ports where beri-beri is to some extent endemic. In one case the interval was three months, and in the other six months. I have a number of references to other cases where the same fact was observed. In the two sets of cases to which I first referred, however, even this explanation is wanting, unless it may be that one of the vessels was infected during the previous winter, and we are obliged to fall back on the conclusion that some infectious form of multiple neuritis occurs in northern latitudes, a view supported by the occasional occurrence of such cases as those described by Rosenheim, and published in the seventeenth volume of the *Archiv für Psychiatrie*, and the cases reported by myself at the meeting of this Society in 1888. Both were severe cases of acute generalized neuritis, running a rapid and fatal course, but without edema.

Wishing to learn whether other cases of this sort had been observed by physicians in the sea-board towns, I sent out a large number of circulars, and obtained fifteen answers: of which those from six physicians — William S. Birge, of Provincetown; S. F. Quimby, of Gloucester; G. B. Stevens, now of Roxbury; S. T. Davis, of Orleans; Benjamin D. Gifford, of Chatham; W. N. Stone, of Wellfleet; and E. E. Hawes, of Hyannis — are of decided interest.

² *Vastus internus* and *rectus femoris*: faradic reaction 6.5, normal 11-12. Sartorius reaction almost normal. All the muscles below the knee reacted to about the same strength of current as above. Galvanic reaction: no local contractions from weak or moderate currents; contractions of twenty seconds duration from strong currents everywhere, +. The peroneal nerve reacted to five milliamperes at first the tibialis anticus responding; but after one or two closures, the contractions died away, and could no longer be obtained.

Dr. Birge reported having seen seven cases, five from one vessel, and two from another, belonging to a fishing fleet which had returned from the Grand Banks. Two of the cases had proved fatal. The symptoms described were evidently of the same character with those in the cases reported by Dr. Shattuck and myself. One of the vessels may have been, however, the same with that from which my first patient had come.

Dr. Quimby had seen the master of a fishing schooner who had these same characteristic symptoms, pain and paralysis in the lower extremities being very marked. The symptoms had come on, as he thought, as a sequel to the influenza of the past winter; but, as I have been looking in vain for cases of typical generalized neuritis following the influenza, I think this explanation is not probable.

Dr. Stevens also called my attention to a case which he had reported in the *Boston Medical and Surgical Journal* of June 16, 1887, occurring in the mate of the bark *Charles G. Rice*, which arrived in Boston May 12th of the same year, from Manilla, after a passage of an hundred and twenty days. The symptoms were essentially diarrhoea, oedema, and (eventually) numbness of the legs without paralysis. The point of particular interest in this case is that the patient was well when he left the port of Manilla, and became ill about a month after that time.

Dr. Davis had seen "a lot of cases where men who had handled fish complained of numbness and great swelling of the hands, and great difficulty in using the extensors." He had considered these due to the irritating action of the fish on the hands. In view of the uniformity of the employment of all the men, this explanation should receive full weight, but the fact that a much larger number of cases seems, as far as we know, to have occurred in certain years than in others, it would seem that neither this nor any other local cause could be the only one at work.

Dr. Gifford had seen one patient, a sea-captain, with symptoms that might, perhaps, be of this character.

Dr. Stone has sent me the notes of five cases, of which at least three may have been of this class. The diagnosis, is, however, not certain, and in some of the cases other well-known causes of general neuritis were present.

The first of the five patients was a man of forty years; a seaman, of temperate habits, and free from constitutional diseases, so far as is known. The symptoms had consisted in progressive numbness of the legs, reaching to the knees, and toe-drop, the whole increasing to its maximum in a few weeks. He improved to a certain point, but never entirely regained the use of the extensors of the foot. This case occurred two years ago.

The next patient was a man of forty-five years, who had followed the sea until the last five years, since when his occupation has been that of a sail-maker, his place of business being on the beach, where he was exposed to wet and damp. Three years ago he was attacked with what appeared to be sciatica, which first attacked one leg, but soon extended to the other, and lasted for a number of months. From this he recovered, but a year ago it returned, and remained for some three months. A short time ago he was again attacked with severe pain in the limbs and feet, and the hands became badly swollen. The swelling subsided after a time in the

hands, but attacked the feet, and at present is spread over the whole length of both legs. The pain is still very severe.

The next case was that of a man of thirty-five; of previously good health, temperate habits, and free from constitutional diseases; he had always followed the sea. His symptoms had consisted in acute onset of pain in both legs, and in general, in the distribution of the sciatic nerve. This pain was worse in the afternoon and evening, as a rule. It subsided in the course of a week or two, but for three months more his muscles were so weak he was unable to walk even with crutches. Four or five months later he could go about with difficulty; and before the end of a year he was able to go to sea again, though still, at the end of nine years, showing some awkwardness in his gait, and using the feet as if they were of wood.

The fourth case was a man of sixty-three. It was a typical case of multiple neuritis, but is not reported here at length, because the habits of the patient suggested that alcohol was the cause of his sickness.

The fifth case was that of a man fifty-five years old; always in good health and a member of the life-saving service crew, his duty being to patrol the beach at night. The beach, when not frozen, was sandy, making the walking difficult. A year ago he came to Dr. Stone, complaining that while walking his toes felt as if there was sand in his shoes, and that this feeling had increased of late. He had noticed that on going down a sharp decline the knees were apt to give way, so that he would fall. Of late the numbness had extended to the calves of the legs, and he had recently had pain through the abdomen to the back, and down the thighs.

Dr. Stone was kind enough to give these notes from his memory, but I thought it better to put them in on account of the obscurity concerning the etiology of this class of cases, thinking they might throw some light upon it.

Dr. Hawes, of Hyannis, writes: "About seven months ago I had a fisherman (I am hospital surgeon of this port) come to me with an ulcer on his leg. I treated it, and he went again to his vessel. He said, 'A few weeks ago I was taken lame, hardly able to stand erect, and I feared I should be paralyzed.' It seems, as he rallied from that, the sore formed. I judged it might be rheumatism, and so can say no more about it. But since receiving your letter I have thought it might be the beri-beri that the man tried to explain, and that the sore might have been an ulcer following the above-named trouble."

To sum up, it would seem that, in 1881, and again in 1889, there were epidemics of this disease, whatever name it may deserve, occurring among the crews of vessels fishing along our northern shores, and that sporadic cases of the kind are occasionally met with.

The cases that I have seen or heard of number fifteen or twenty, and embrace the greater part of the crews of five vessels, three of them from the Grand Banks, and one from off Block Island. This aggregate does not include Dr. Shattuck's cases nor those described in the letters.

I have received a letter, within a few days, from one of the patients whose case I have reported, saying that he still suffers from numbness of the feet and toe-drop, although it is now about — years since he was first attacked, and saying, further, that another of the crew is still quite sick. It is possible that, either primarily or secondarily, the spinal cord

was affected, as well as the peripheral nerves. He further notes that his vessel was a mackerel fisherman, while those off the Grand Banks were cod fishermen.

The possibility of infection from the fish should be considered, and the letter from Dr. Davis is interesting in this connection.

This patient also says that the vessel on which he and his crew were employed had not at any time been engaged in the Southern trade, so that this possible cause of infection, which was present for Dr. Shattuck's cases, may be set aside, so far as this group is concerned.

A SUCCESSFUL CASE OF URETERO-LITHOTOMY FOR AN IMPACTED CALCULUS.¹

BY A. T. CABOT, A.M., M.D.,

Surgeon to the Massachusetts General Hospital, and Instructor in Genito-urinary Surgery in the Harvard Medical School.

The following case is interesting, first from the fact, that so small a calculus should lodge for so long a time in the ureter without progressing toward the bladder; secondly, on account of the serious constitutional disturbance that it caused; and lastly, from the success that attended its removal.

The patient, rather a slight man of forty, was under the care of Dr. S. W. Driver, of Cambridge, and was seen on the 22d of April, 1890, in consultation with him, and with Dr. J. T. G. Nichols and Dr. Walter Ela.

Six years before, he had been under the care of Dr. Driver for an inflammation of the bowels, which was mainly located in the right side, and was probably connected with the appendix. Since that time he had enjoyed good health with the exception of occasional attacks of colic, for which he sometimes consulted the doctor, and which seemed to be due to disturbances of digestion.

For the past three months his bowels had been somewhat loose, and during this time he had had seven or eight sharp attacks of pain which came suddenly and passed away suddenly, and were all referred to the left side, in the front of the abdomen, at a point just above the middle of Poupart's ligament. This pain did not run down the thigh nor into the scrotum, although retraction of the testicle was noticed in some of the paroxysms.

None of these attacks were severe enough to demand medical aid until April 16th. On that day he was seized with a sharp, sudden pain, like that in the previous attacks, but much more severe, and enduring persistently, not passing off as the others had done. He was then seen by Dr. Driver, who found him suffering from very severe paroxysmal pain. The abdomen was soft and flaccid, not tender, except slightly in the left hypogastrium, at the point where the pain was especially felt. Subsequently, a very sensitive spot was found in the back, midway between the crest of the ilium and the lower rib. This last spot of tenderness was constant, not disappearing during the intermissions, and the pain on pressure was very acute.

He was treated with full doses of opium, together with the frequent administration of ether when the paroxysms were especially severe. In this way he

passed five days, suffering pain most of the time, though with occasional intermissions of considerable length.

Examination of his urine showed it to contain a few hyaline and granular casts, and on April 20th considerable pus was found in it.

On April 21st, he had for the first time, some fever, the temperature going to about 101° F., and the pulse being above 100. Except for this he had a good day, with but little pain.

Early in the morning of April 22d an unusually sharp attack of pain began, and this lasted until we saw him, at one o'clock; the only relief obtainable being by the persistent inhalation of ether. The moment that he began to be conscious, the crying out from the pain was constant.

On this day he began to vomit, and his pulse was weak and frequent.

At the time of consultation the urine was perfectly clear. He was partially under the influence of ether when examined, so that his sensations could not be accurately determined, but it was quite evident that the point of extreme tenderness was in the lumbar region, midway between the ribs and pelvis. There was also a slightly increased sense of resistance felt over the renal region, but it was thought that this was very probably due to muscular rigidity.

Although there had been no movement of the bowels since the beginning of the attack, the absence of sensitiveness or distension in the abdomen made it pretty clear that the intestines were not responsible for the present illness. On the other hand, the character and location of the pain, with the tenderness in the lumbar region, pointed to the kidney as the probable source of trouble; and even in the absence of disturbances of micturition, and of the characteristic pain shooting into the testicle, it was thought that a calculus in the ureter was probably the correct explanation of the symptoms. The varying condition of the urine, now containing pus and again clear, made it seem that a certain amount of urine leaked around the calculus, and the presence of casts in the urine showed that the kidney was already suffering from the obstruction.

In view of the rise of pulse and temperature, and the distinct and rapid loss of strength under the severe pain and the appearance of vomiting, it seemed wise to attempt to remedy the condition by an operation. The possibility that there might already be an inflammation, with pus forming around the site of the calculus, made the operation seem the more desirable.

The patient was accordingly etherized, and an incision was made along the outer edge of the quadratus lumborum muscle, from the lower edge of the twelfth rib to the crest of the ilium. The space between the rib and the pelvis was very narrow, even after the trunk was bent strongly over pillows.

The kidney was found to lie very high under the ribs so that only its extreme lower end could be brought into view. A needle carried through the kidney, in the direction of the pelvis, met with no resistance and encountered no calcareous matter. An exploration was then made along the course of the ureter, as nearly as that could be determined, and in the deep part of the wound about two inches below the kidney, a small hard mass was felt, and on examination it was found to be lying in the ureter. With a blunt hook the ureter was drawn forward into view,

¹ Read before the Boston Society for Medical Improvement, May 12, 1890.

and exploration with a fine needle showed this mass to be a little calculus. It was readily removed through a little longitudinal cut in the line of the ureter.

A probe was then passed through this opening, up into the pelvis of the kidney, and downwards about five or six inches towards the bladder, without encountering any other calculi. A drainage-tube was laid in close contact with the opening in the ureter, and another was carried up behind the loose tissues around the kidney. The angles of the wound were brought together with sutures, but it was left largely open. The patient bore the operation well.

After recovering from the ether, the sharp paroxysmal pain had wholly disappeared, although there was still considerable dull pain in the same region as before.

The first urine after the operation was examined with the following result: Color, high; specific gravity, 1,019; sediment considerable, containing many large and small, hyaline and granular casts, a few pus cells, and occasional red blood cells. This specimen contained no albumen.

Two days later, on April 24th, the specific gravity was 1,023, and there was a large trace of albumen. The sediment still contained hyaline and granular casts, but far less abundantly. There were also still a few old blood cells, and very few pus cells.

On April 25th, the patient had a sharp attack of pain in the morning, which he located in the old place. This was relieved by the subcutaneous injection of morphine, and at the dressing, the tube which reached down to the ureter was shortened, with the idea that it might possibly be obstructing the flow of urine. The next day, the dressing, which had been dry since the day after the operation, was soaked with urine, and there had been no recurrence of pain. The patient was beginning to take food well, and was looking much better.

On May 2d there was another slight attack of pain, and this too was accompanied by the escape of urine through the wound. From this time the wound steadily closed, there was no more leakage of urine nor pain in the course of the ureter. The patient steadily gained in flesh and strength. Finally, on May 12th, (three weeks from the time of operation), the last tube was removed, and the patient was up and out of bed.

The calculus removed in this case was a little rough phosphatic and carbonate stone weighing two grains.

A stone impacted in the ureter is a condition by no means devoid of danger. Cases are reported, in which, even although the other kidney was apparently healthy, a fatal suppression of urine has followed the stoppage of one ureter in this manner. Israel, who has reported such a case, regards the suppression as due to a reflex inhibitory action, the starting point of which, is the irritation of the ureter by the calculus; and he cites cases to show how much the secretory function of the kidneys is under the control of the nervous system. Urethral surgery furnishes further illustrations of this sort of inhibitory action due to distant irritation, in the cases of interference with the function of the kidneys after operations, often of but little severity, on the urethra.

Besides this general danger of interference with the secretion of urine, the kidney on the affected side

often becomes seriously diseased through changes directly due to the obstruction to the escape of urine. These changes may take the form of a hydronephrosis, or of an interstitial nephritis. The formation of a pyonephrosis under these circumstances too, is by no means uncommon.

That the kidney in the case reported had already begun to suffer, was shown by the presence of casts and pus in the urine. Unfortunately, no exact measure of the daily quantity of urine had been made, but it had been noticed to be diminished in amount, and this diminution was due, no doubt in part, to the obstruction of the calculus, and partly to the reflex irritation, and to the congestion of the kidney.

It would seem wise to operate for the removal of an impacted calculus as soon as any constitutional symptoms show themselves, or when there is evidence that the kidney on the affected side is beginning to suffer degenerative changes. An operation for the removal of a calculus, if done early, is much better borne than when done upon an exhausted patient, late in the progress of the disease. It may too save a useful kidney which would be lost by delay.

It is often difficult or impossible to determine beforehand the position of a calculus in the ureter. The point of greatest tenderness should be sought for with a good deal of care. In the case just reported, the stone was found directly under the point of constant tenderness in the loin. When the stone is lower down in the ureter, it is sometimes possible, particularly on a thin patient, to find a constant tender point where the calculus rests by deep pressure over the line of the ureter through the anterior abdominal wall. In a woman, the calculus may be felt through the vagina, if it has lodged in the lower part of the canal. Such a case has recently been seen by the writer, where the calculus could be distinctly felt lying close to the left side of the cervix uteri, and a little behind it.

Israel proposes the following incision for exposing the ureter extra-peritoneally: Commencing at the anterior edge of the sacro-lumbar mass of muscles, a finger's breadth below the twelfth rib, the cut is to be carried parallel to the rib as far as its tip; then turning down towards the middle of Poupart's ligament till the line of usual incision for tying the iliac artery is reached, then turning towards the middle line, and ending on the external border of the rectus muscle. According to the seat of the calculus, the incision will be made on the posterior, middle or anterior third of this line.

When, as is sometimes the case, the calculus is actually lodged in the vesical opening of the ureter, it may be reached by a supra-pubic incision in the case of a man, or by a dilatation of the urethra in the case of a woman. This lowest portion of the ureter is also quite accessible in woman through the vagina, and in the case above alluded to, in which the calculus could be felt alongside of the cervix uteri, it was removed by incision in the vault of the vagina, and was found to weigh 190 grains in the wet state just after its removal.

This case, which is not yet completed, will be reported more fully at some subsequent time.

The favorable course of the case which gave the title to this paper, shows that a longitudinal cut in the ureter will quickly close, just as similar incisions do in the urethra. No attempt to apply sutures to

the wound in the ureter were made. The wall was so thin that a suture would necessarily have entered the canal where it would be likely to have given rise to the deposit of urinary salts, the calibre would have been narrowed by any gathering together of its walls, and the ureter lay so loosely in the tissues about that, unlike the urethra, it could not be drawn together by stitching the tissues down close to it, and lastly, it lay so deep that it would have been almost impossible to apply sutures without a much more extensive separation of the tissues about it.

A PLEA FOR PHYSICAL DIAGNOSIS.

BY J. HILGARD TYNDALE, M.D., NEW YORK.

BROADLY speaking, we recognize in diseases of the lungs two main pathological divisions. *Rapidly developing processes*, of which croupous and catarrhal pneumonia and all forms of pleurisy are examples; and *slowly progressive processes* — represented by shrinkage of connective tissue (fibrous phthisis), caseous infiltration, and the formation of cavities. Tuberculosis — the presence and rapid proliferation of the bacillus tuberculosis — is to be classed either as an acute invasion or as a final climax to chronic conditions.

To determine the existence of any of the above conditions we resort to auscultation and percussion as a means of diagnosis. In speaking of the methods by which the average physician arrives at a conclusion by means of auscultation and percussion, I will confine my remarks to diseases of the lungs to illustrate the pathological condition — leaving out the heart and abdominal cavity, pass by palpation and inspection as aids to diagnosis, and confine myself to auscultation and percussion alone.

Given, patients whose subjective symptoms point to acute or chronic disease of the lung. Given, also the general practitioner, who is about to examine him. I refrain from calling attention to the average *method* of examination; auscultating and percussing over clothing — a most reprehensible proceeding — or how ear and fingers are used to determine sound, or whether or not it is always best to use hammer and stethoscope. What will the attending physician look for?

Chiefly, and often only, for *moist or dry râles* — the so-called adventitious sounds. If they are present, the diagnosis is largely, if not entirely, based upon that finding. Or going a step farther, he will determine the *presence or absence* of the two normal respiratory sounds — the vesicular and tubular (bronchial). Thus far auscultation. As to percussion, he will determine whether the percussion note approaches the norm or, if not, whether there is *distant* dulness or an equally readily recognizable tympanitic sound.

In active processes in the lung, a correct diagnosis can be, and often is, thus arrived at, more especially when the disease is accompanied by more or less fever. So far, so good, for the patient as well as for his medical attendant.

Again, it must be borne in mind that a practitioner with an extensive practice cannot be expected to devote a very great portion of his time to one patient. And to make a correct physical diagnosis in disease of the respiratory organs, and to note its progress from day to day, requires time.

The great bulk of cases in which the subjective symptoms of a patient point to lung trouble, however, are not of an acute nor of a very pronounced character. I venture to assert that seventy per cent. of all chronic lung troubles present no such readily recognizable physical signs as those mentioned above.

All progressive pathological conditions of the lung, which we sum up under the comprehensive heading of pulmonary consumption, finally cause death by an invasion of acute tuberculosis, by purulent infection, or by heart-failure, or several of these elements combined. Years often elapse before this finale is reached. During all this time the slowly destructive process goes on, even though the general nutrition may be in great measure, unimpaired.

We are all familiar with the forms in which these processes present themselves. They are, broadly speaking, as follows:

(1) *Shrinkage*. — The result of connective tissue processes around the bronchi and in the pleura. The latter is by far the most frequent starting point of all phthisical conditions.

(2) *Filling up* of the bronchioli, and consequent obliteration of vesicular structure by inspissated mucus and pus, and by epithelium — so-called cheesy infiltration.

(3) *Excavation*. — The formation of one or more large cavities, or a great number of small ones.

Neither of these three conditions is in itself a deadly agency, but they are the potent factors which slowly drift the patient toward death by one feature common to all: The gradual but certain *diminution of the respiratory surface*, necessary for the oxygenation of blood, and the existence of the patient. In other words, they steadily encroach upon the territory requisite for respiration. This is one of the most potent truths in pathology, and should ever be borne in mind.

Now whenever shrinkage, infiltration or excavation are present to such an extent as to seriously impair the requisite respiratory surface, then the physical signs mentioned above become readily recognizable — namely: moist or dry râles; or distinct absence of vesicular murmur, and tubular respiration where the vesicular should be heard. Also dulness or exaggerated resonance on percussion. These are the signs to which I have drawn attention as being easily recognized even by an unskilled observer.

And now I come to my actual plea for physical diagnosis. I reiterate that the great majority of phthisical patients present no such tangible evidence of their lung condition as mentioned above — never in the incipient stages, and hardly ever before weeks and months have elapsed.

This plea is not intended as a handbook of physical diagnosis. Hence the necessity of confining myself to broad facts. The physical signs of all forms of pulmonary phthisis are caused by one of two main pathological elements.

(1) *Changes of structure in the pulmonary and bronchial tissues themselves* — whether by connective tissue shrinkage, cheesy infiltration, or the invasion of tubercular bacilli, or an intermingling of several.

(2) *Adhesions of the pleura*, which act as a mechanical hindrance to respiration, by binding down the lung.¹

¹ The credit of bringing forward, and upholding this most important factor in lung troubles, is almost entirely due to Prof. James E. Leaming, of this city.

For the purposes of this paper it is not necessary to include percussion nor the auscultation of the voice. Auscultation of the respiration will illustrate all I wish to say.

In order to hear what is going on in the lungs, it is necessary to have at least a faint idea of music, not that the respiratory sounds are musical notes, for they are not, but they have this in common with musical tones: They have a certain *quality* (*Tonart* in German), a *pitch* of this particular quality and, last but not least, a *rhythm*, a fixed time (tact), as has any melody. In the normal condition, the respiration should be: (1) As to quality: Rustling vesicular murmur and tubular respiration, according to locality. (2) As to pitch: A moderately low one. (3) As to rhythm: Inspiration (audible) no pause and an expiration (almost or altogether inaudible).

The deviations from this normal standard, however small, are what constitute the physical signs in the early stages of consumption. Right here it is necessary to emphasize, however, that there is no *patent* norm for all individuals, and that, therefore it requires more skill to determine what apparent changes are *within physiological limits*, than to find actual deviations from the norm.

While in the act of auscultating, the ear or stethoscope should not be removed until quality, the pitch of this quality, and the rhythm of the respiratory movement are fixed in the listener's mind.

Let the physician remember that all three of these elements have their *norm*, a mere *deviation* from the norm and *abnormal sounds*, either accompanying or supplanting them altogether. We are here dealing with the deviations only. They are in short:

(1) As to quality: Exaggerated, diminished, absent.

(2) As to pitch: Higher or lower than that which accompanies normal vesicular or bronchial breathing.

(3) As to rhythm: An interrupted inspiration (misnamed cog-wheel respiration); a pause between inspiration and expiration, which ought not to be there, a prolonged and audible expiration.

The next duty of the auscultator is to find whether these deviations from the norm are caused by mechanical hindrance only — in other words, by a binding down of any portion of the lung by pleuritic adhesions, recent or old.

To determine whether slight deviations from the norm of quality, pitch and rhythm are within physiological limits or, if not, whether they are caused by mechanical hindrance in the shape of pleuritic adhesions and their traction, or whether these slight deviations are the true signs of incipient phthisis in an already shaky subject — to determine these fine points is the quintessence of physical diagnosis. A failure to appreciate these fine distinctions in acoustic signs may lead to a plan of treatment which is bound to prove futile, and perhaps fatal.

In connection with this subject of careful physical diagnosis, let me draw attention to two papers by Prof. James R. Leaming, in which this question is handled in a far abler manner than I am able to do it. The one is entitled: "Acoustics applied to the human chest in physical diagnosis,"² and the other: "Interpleural pathological products; their cause, significance and specific relationship to pulmonary phthisis."³

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

O. O. SEARS, M.D., SECRETARY.

REGULAR MEETING, May 12, 1890, the President, DR. W. L. RICHARDSON, in the chair.

DR. E. H. BRADFORD read a paper on

THE TREATMENT OF LATERAL CURVATURE.¹

DR. BOLLES: This paper has been a very interesting one, and one eminently practical in its character. I am very much obliged to Dr. Bradford for bringing the apparatus. Some of the pieces, it seems to me, are particularly important and ingenious. This couch with a roll on it I should think might be useful to children not really subject to spinal curvature, but who have weak backs. In regard to one important piece of apparatus of which the doctor spoke I should like to ask him to be a little more explicit. I refer to the Morris form of chair. Perhaps he will tell us whether there is a child's size of Morris chair in the market.

DR. BRADFORD: I found difficulty in obtaining one, but I finally found one at Keeler's, which, though not strictly speaking a child's chair, could be used for an adolescent.

DR. CABOT: I have nothing to add. I should like to ask if this slope that the Morris chair gives is better than sitting upright. Children are constantly told to sit up straight.

DR. BRADFORD: The old-fashioned straight-back chair was not deep in the seat, and a child could not curl up in it. What is required is an easy chair in which the child with a weak back will be comfortable, and can remain two or three hours without being watched. It is for this class of children that you want a recumbent chair. The straight-back chair does very well for a short time, but in feeble children it would not answer.

DR. WATSON: I would like to ask Dr. Bradford how often lateral curvature occurs as the result of one leg being shorter than the other, a matter about which Dr. Taylor has spoken a good deal formerly, and, if that is ever found to be the case, whether he would not treat that condition by raising the sole of the foot of the short leg. I would also like to ask with regard to the possibility of relapse in case of a moderately flexible curvature in which you have succeeded in straightening the back, and how long should treatment be kept up to ensure against relapse.

DR. BRADFORD: I did not lay much stress on the etiology because that is a long subject and has been recently discussed here. The cause of lateral curvature is the superercent weight falling on the spine held out of line. If one leg be shorter than the other a fixed lateral curvature does not, of necessity, follow. For lateral curvature to result, the condition of the bones must be such as to weaken under superercent weight. Given a case of hip disease or paralysis in which one leg is shorter than the other, a lateral curvature will result if the condition of the bones is analogous to that causing knock-knee.

As to how long treatment should be continued and as to the danger of relapse, no one can, I think, state definitely. The only rule I have is this: If the patient

¹ Publication deferred.

has attained its height as estimated by Bowditch's tables, if the general condition is good and the flexible curve has been corrected, I should say there is very little danger of relapse. If the child is approaching puberty, belongs to a tall family, has grown fast and grown thin, I should give a guarded prognosis as to relapse.

DR. F. B. HARRINGTON: How early in infancy do you see lateral curvature, and is there such a thing as congenital lateral curvature?

DR. BRADFORD: Congenital lateral curvature exists, but is rare. In rare instances there is also a defect in the spinal column. One such case was reported by Dr. Gage of Worcester. The earliest case I have met was in a markedly rachitic child, in which case there was a history of injury at birth from the use of forceps, producing paralysis of the right arm. When the child began to be lifted it sat on one side, and, being profoundly rachitic, a very severe osseous curve had resulted by the time the child was nine months old. Lateral curvature is sometimes seen in children who are carried by the mother on one arm more than on the other. I don't think I have ever seen a case of true congenital lateral curvature apart from the cases in which there is deficiency in the structure of the bones,—that is, where the vertebrae were deficient. I have seen cases called congenital lateral curvature, in which it seemed to me the curvature developed subsequent to birth.

DR. HARRINGTON: Would infants be treated on the frame?

DR. BRADFORD: Yes, and by the avoidance of faulty attitudes, the child should be made to lie so as to make the convexity concave, and on a frame.

DR. NEWELL: I think this is a splendid demonstration, for which we are much indebted to Dr. Bradford. I would like to ask him his opinion about woven wire and felt and leather corsets.

DR. BRADFORD: I should think the woven wire corset might be an excellent appliance. Before it was advertised I had one made. The main requisites for a corset are that it should be light, cheap and suited to the case. I don't see why the wire corset should not be made to answer the purpose. Whether it is cheap I can't say. I don't think it has any great advantages, and I don't think it is inexpensive. I have tried it in only one case. Felt, which was introduced some time ago, is heavier and more clumsy than the leather corset. The reason I have for using leather is that it is light, cheap, and I can get it made. Besides these, Dr. Phelps of New York has used wood-pulp. There is a most excellent corset made in Philadelphia which I think is a form of felt. It is light, extremely hard and rigid. I imagine it may be expensive.

DR. NEWELL: Can these leather corsets be made in Boston?

DR. BRADFORD: A harness-maker on Eliot Street makes them. You send a plaster cast and he makes it of leather from that. The cost is seven or eight dollars, and that is as cheap as anything you can get.

DR. NEWELL: Do you account for the deviation to the right by the muscular element?

DR. BRADFORD: That is a difficult question to answer. I think it is easily explained by the fact that persons use the right arm more than the left. If you watch the attitudes of students writing, you will notice that they all raise the right shoulder, not only because they use the right hand in writing, but because they

can't write very well otherwise. I think that would explain why this is the normal curve.

DR. W. L. RICHARDSON: Has Dr. Bradford noticed whether growing children with lateral curvature of the spine frequently have deformed pelvis, apparently as a result of it?

DR. BRADFORD: I have not made examinations with regard to that point.

DR. RICHARDSON: What would the probable effect be?

DR. BRADFORD: In extreme cases I think such a result might follow; in light cases I don't know.

DR. A. T. CABOT read a paper on

A CASE OF URETERO-LITHOTOMY.²

DR. DRIVER: In this case there was a possibility that the diagnosis might be obscured by the previous history of the patient. As the patient had had perityphilitis and was subject to violent attacks of colic, I supposed, when called, that it was one of his old attacks. I found, however, that it varied very much from them. The seat of the pain was low down, above Poupart's ligament, and passed backwards and upwards, and suggested at once the diagnosis of renal colic, which was made provisionally, although many of the usual symptoms of renal colic were wanting. The fact that he had long continued diarrhoea, at times peculiar attacks of pain, and the fact that his health was deteriorating, suggested the possibility of other things; still the treatment was intended to cover all the possibilities. The first thing one would think of would be the possibility of obstruction. That was eliminated by the examination under ether. Then there was the possibility of aneurism low down in that very region, attended by sciatica. There developed Wednesday, Thursday, and Friday, great tenderness over the sciatic nerve. That might represent the pain that is often felt going down the leg in the case of renal colic. In watching the case we eliminated these things. The pulse kept down until the very last day. The violence of the case surpassed everything which I have seen in the nature of renal colic, as much as the tornado surpassed the gale. I had watched the case from Wednesday to Monday. On Monday the pulse was 76, temperature normal, no special tenderness, and still that sharp tender spot behind and the tender spot on the sciatic nerve,—a condition that made us feel that the calculus was going through; and we decided if the symptoms returned again to call Dr. Cabot. It was a very puzzling thing to the general practitioner up to that time. I examined the urine from day to day, and pus was found every day. The three great factors in this case were the violent pain which was like nothing but renal colic, persistent tenderness at one spot just below the kidney, and the pus from the first. These things, I suppose, were what determined the diagnosis in the minds of the gentlemen who saw the case with us.

DR. ELA: I am very glad to hear Dr. Cabot's report of this very interesting case, and the more so because it verified what we thought was the probable cause. I think he is to be congratulated on the successful issue of the case. It is one of the best operations I ever saw. At the time of the operation the urine contained granular and hyaline casts, and the quantity of pus was fully one-fifth in volume, whereas the next day after the operation, the urine was very

² See page 217 of the Journal.

clear, so that one would think it could not have come from the same patient. A relative of the young man told me that the mother had also passed calculi, and from the size of the stone and its appearance one would think it was of the uric acid variety. Perhaps Dr. Cabot will tell us what the analysis showed.

DR. CABOT: The stone was extremely small, that is, the part removed for analysis. Professor Wood was kind enough to take a little of it and test it, and it proved to be phosphatic instead of uric or oxalic acid, as we expected. The stone weighs only two grains, and the wonder is that so small a stone lodged in one place and staid there so persistently. One reason may have been that the function of the kidney was interfered with by the reflex inhibitory action, and the flow of urine from that side was but slight. I advance that simply as a theory to account for it. The stone is somewhat irregular, so that a little urine might leak by it.

DR. WATSON: Dr. Cabot's paper suggests many interesting questions for discussion, a few of which only I will touch upon, prefacing my remarks by congratulating him upon the success of what, I think, must be called a remarkable surgical procedure. Impacted calculi have been successfully removed from the lower end of the ureter, and of course, their removal from the pelvis of the kidney by nephrolithotomy has been frequent. I do not, however, recall at this moment an instance in which the surgeon has, with intention, opened the ureter below the pelvis of the kidney and successfully extracted stone; and if this is new departure, it certainly establishes a valuable precedent. I wish to note, though I have no satisfactory explanation for the fact, the singular immunity from serious results (presented in some patients) of total, or almost total, suppression of urine in cases of impacted calculus, of which I recall one case in which, with the exception of a few drops of urine in each twenty-four hours, anuria lasted eleven days, the patient showing no urasic symptoms of importance, and making a perfectly good recovery thereafter; and of which a number of similar instances have been recorded.

Another matter in the *diagnosis* of renal calculus, to which I called attention last year, in reporting to this society five cases of renal calculus, of which it was true, is that the urine *may* afford no guide to determining the presence of stone in the kidneys, as it, in the presence of stone, *may* present absolutely no abnormal characters. The importance of Dr. Cabot's operation in such cases as the one he has reported, is enhanced by the knowledge that, should an impacted stone remain for a long period in the ureter, even if finally and spontaneously passed, it may, beyond the damage done to the kidney during its stay in the ureter, cause its still further disorganization by giving rise to stricture of the ureter at the point at which it has rested, as in a case of stricture of both ureters, hydro-nephrosis and death, which I reported here some four years ago.

In general, in cases of renal calculus, in which the stone fails to pass, I think the tendency here, on the part of the general practitioner, and often of the surgeon as well, is to postpone operative interference too long, especially in view of the successes obtained by Mr. Morris, of England, and others who have pursued the bolder course.

DR. NEWELL: I think this is a very brilliant case, and very interesting from its rarity and for a good

many other reasons. I was rather surprised when I saw the calculus. I think it is a very large one to pass through the ureter. I happen to have injected the ureter a good many times, and it seems to me that this calculus in the normal ureter would be a pretty good-sized stone to get through. I always found it hard to get in an injection-pipe of over one-eighth inch. I think one very interesting point is as to the definiteness with which you can locate a stone by pain. I suppose there is never any exception to the rule, that in renal colic, whether in the kidney or in the ureter, the pain is on the side where the stone is found. I would like to ask Dr. Cabot what he thinks of the value of local tenderness as a general guide for the location of a calculus.

DR. CABOT: That pain in the leg is very common with stone in the kidney.

DR. DRIVER: The pain was never in the leg. He had great tenderness on pressure. The factors were tenderness, pain and pus.

DR. NEWELL: I think the case would show that tenderness on pressure may be an important factor in locating the stone.

DR. A. T. CABOT reported two cases of

OLD ANTERIOR DISLOCATION OF THE HUMERUS, which occurred in women of advanced age, both patients being seventy years old. In one the arm had been out for three months, and in the other for nine weeks. These cases were reported in order to draw attention to the value of Kocher's method for the reduction of these dislocations. The manipulation was described as follows: The arm being laid along the side parallel with the axis of the body, the elbow is bent to a right angle, and then, with the fore-arm as a lever, the arm is forcibly rotated outward until resistance is met. Then, keeping the arm still strongly rotated outward, the elbow is carried forward close to the body until it rests over the epigastrium. The hand is now carried to the opposite shoulder, and if the manipulation has been successful the head of the bone is found to be in place. This manoeuvre, as described, can usually in fresh cases be practised without ether, and was recently perfectly successful in reducing such a recent dislocation in a powerful young man. In old cases, when the bone has been out of place for some time, and has become adherent in a faulty position, as was the case in the two old women, the adhesions must first be broken up by forcible rotation and movements in various directions. Kocher's method has the advantage that, while it is usually successful, the operator requires no assistance, and the expenditure of strength is much less than in any of the traction methods.

AMERICAN DERMATOLOGICAL ASSOCIATION.

FOURTEENTH Annual Meeting, held at Richfield Springs, New York, September 2, 3 and 4, 1890.

THE PRESIDENT'S ADDRESS.

DR. PRINCE A. MORROW, President, considered in his address the present position of dermatology in this country. He thought there was abundant cause for congratulation. In 1876 only twelve of our medical colleges pretended to give instruction in this special department, whereas to-day, as he had learned, through

replies to a circular letter, dermatology is recognized in the teaching faculty of eighty-six colleges. This might, perhaps, indicate not true, but in part a mushroom growth, for there are reasons to believe there were many defects in the method of teaching, if not in the qualification of some of the instructors. For successful teaching of diseases of the skin two conditions were necessary, namely, capacity in the instructor, and abundance and variety of clinical material. He doubted the capacity of the teachers in some of the schools; while it was a certainty that in many the clinical material was inadequate. In some of the large cities this material was so dispersed as not to be available. For a thorough study of cases and results of treatment there should be a central hospital. With regard to methods of instruction, dermatology should be retained for advanced students in medical colleges, and its study should be obligatory. If there were not abundance of clinical material, he thought it a question whether it would not be best to leave this branch of medicine to post-graduate schools.

Speaking of nomenclature, he thought there was something of a neologistic craze, which should be discouraged. An essentially new disease, it was true, required a new name, but many of those introduced the past few years would not likely prove permanent. He also suggested the propriety of introducing some special subject for discussion at each of the annual meetings.

OBSERVATIONS ON PRURIGO, CLINICAL AND PATHOLOGICAL.

DR. R. W. TAYLOR, of New York, in a paper on this subject, said that Dr. Campbell read a paper at the first meeting of the association, and it appeared then that there were only six cases in the combined experience of all present. Interest had been excited anew since the reading of Dr. Zeisler's paper last year, in which he said he had seen twelve cases in Chicago. Others present brought up the number to eighteen. But he believed the disease to be more common in America than these figures would indicate; that many cases were probably mistaken for eczema, scabies, pedicularis, impetigo, etc. The general profession had no plates to compare cases with, and to supply this want he gave the history of a case in detail, with photographic illustrations.

Some points in the history of the case were as follows: A girl, aged nine years, healthy when the disease broke out, of healthy parents, who were in good circumstances and in healthy surroundings. When four years old the girl began to scratch, and the appearance of little red pimples on the face, forearms and legs, led the parents to attribute them to mosquitoes (they were then spending the summer on Staten Island). The affection continued to recur at certain seasons, worst in the winter, every year until her visit to Dr. Taylor which was in January last. The expression of the face was rather dull, the color of the typical white, somewhat ashy hue, of prurigo. Over the forehead, temporal region and cheeks was a copious eruption of small conical papules, some whiter than the skin, others of rather yellowish hue, and others capped with a blood-crust, the result of scratching. They were not developed on the site of sebaceous glands. There was no marked dryness or want of vitality in the hair, as he had seen in severe cases. There was slight mealy desquamation in the scalp, as

pointed out by Hebra. The eruption did not appear on the neck and nucha, but began to develop where the shoulder merged into the neck. The principal eruption was on the back of the hand and forearm, and on the outer and anterior surface of the legs, where the papules were as large as a split pea; some on the arm, buttocks and thighs. They were scattered without semblance of groupings, conical in shape, firm, some of the color of the skin, others of reddish hue, others capped with a blood-crust. Variations in the appearance of the disease were observed and described under certain complications, and shown in photographs.

Dr. Taylor also read the report of Dr. Ira Van Giesen, who had studied sections under the microscope.

A CLINICAL STUDY OF PRURITIS HEMIALIS, WINTER ITCH, FROST ITCH, ETC.

DR. W. T. CORLETT, of Cleveland, read the paper. The affection under consideration was first pointed out as a disease, *sui generis*, by Dr. Duhring, and about the same time by Jonathan Hutchinson, since when it had been little written about. It is seldom seen save in certain localities; is seen in the Southern States only during cold waves; is seldom encountered in the clinics at London; on the southern border of Lake Erie. The writer's home being Cleveland, he could say the disease was well defined and not uncommon. He related three cases illustrating different points of interest connected with the disease. In one it had recurred during the frost season for over twenty-two years; in another the eruption had the appearance at times of urticarial patches, two or three inches in diameter, confined to the extremities, subsiding in about ten minutes, leaving for a while a dark, yellowish spot. The third case was in a negro, showing that that race was not exempt. The writer's experience went to show that the state of the general health had no appreciable effect on the pruritis; that the local irritation of the clothing, although capable of aggravating the malady, was not, of itself, able to produce it; meteorological conditions appeared to be the main etiological factors. These were most potent with a low temperature, low humidity, and a wind blowing from the northwest. These influences were favorable to evaporation, and the low temperature reduced the glandular activity of the skin to the minimum. As a consequence the skin became harsh, the peripheral nerves were irritated, and the disease was induced. He did not think the primary irritation could be central, else in time it would give rise to a less fleeting disease. It was not infrequently associated with other neuroses of the skin. These neuroses having, however, no influence, save, probably, in showing the peculiar susceptibility of the nervous system.

The treatment was largely palliative. Change of climate was best if possible. Internal remedial medication seemed to have little effect. Locally he had used with advantage ichthyoil and resorcin. Choose a warm and moist climate.

A STUDY ON PRURITUS.

DR. E. B. BRONSON, of New York, from a more or less theoretical and argumentative paper on this subject, thought he was warranted in drawing the following conclusions:

- (1) That there is a sense of contact independent of the sense of prehension.

(2) That this sense of contact is the sense disturbed in pruritis.

(3) That it concerns, primarily, simple cutaneous nerves, or nerve endings situated superficially and probably in the endermis.

(4) That disturbance in pruritis is of the nature of dysesthesia due to accumulated or obstructed nerve irritation, excitation with imperfect conduction of the generated force into correlated forms of nerve energy.

(5) That scratching relieves itching by directing the excitation into freer channels of sensation, sometimes, especially when severe, substituting for the pruritus either painful or voluptuous sensations.

(6) That the voluptuous sensations which may attend pruritis are a manifestation of a generalized aphrodisiac sense, representing a phase of common sensation that has its source in the sense of contact.

CASES OF CUTANEOUS TUBERCULOSIS, WITH HISTOLOGICAL STUDIES.

DR. J. T. BOWEN, of Boston, read a paper containing the histories of a number of cases of cutaneous tuberculosis, together with histological studies, and expressed the view, also entertained by Dr. White, through whose courtesy some of the cases were seen, that several affections of the skin not yet recognized as inoculable would be proven to be so, and their relation to tuberculosis be demonstrated.

REMARKS ON THE TREATMENT OF DERMATITIS HERPETIFORMIS.

DR. L. A. DUHRING, of Philadelphia, said that the several papers published by him on dermatitis herpetiformis during the past five years had contained no reference to treatment. Having now reported ten or twelve cases, it seemed appropriate to now speak of the treatment of this exceedingly rebellious disease. Each group of cases based on the etiological factors at work, required special handling. A speedy cure was not to be looked for. It must be remembered that the disease, as a rule, was multiform in character, and the several varieties naturally called for different formulae, especially as to the strength of the remedy. His experience had been that milder remedies were called for in the erythematous than in the vesicular and bullous forms. A difficulty to contend with was the tendency of the disease to repeat itself, a new crop coming out before the older disappeared. Almost all his cases had been chronic, and previously undergone all manner of treatment. He had long since arrived at the conclusion that most benefit was to be derived from stimulating applications, especially those which acted as revulsives — tar, carbolic acid, sulphur, thymol, ichthyol, resorcin, etc. That which had proved of greatest value in his hands had been sulphur ointment, two drachms to the ounce, applied by thorough and long rubbing so as to make a positive impression upon the skin, causing, as it were, local shock. Special emphasis was placed upon the manner of making the application. Internal remedies had proved of little avail in most cases.

A CASE OF ATROPIA MACULOSA ET STRIATA FOLLOWING TYPHOID FEVER.

DR. F. J. SHEPHERD, of Montreal, presented the history of the case, illustrated by photographs. It occurred in a boy of fifteen years, who was brought to

the hospital with typhoid fever. During the course of the disease he was delirious, and had epileptic attacks. Macular lines formed, extending across the patella, and around the anterior aspect of the thigh to near the middle, some being several inches long. They were of reddish color, became paler, not distinctly shiny, and were grooved. The boy left the hospital without his knowledge. The interesting point in the case was the occurrence of the atrophic lines in a boy during acute fever. He did not think their presence could be accounted for as they were in edematous subjects, by stretching. There seemed to be a nerve element in the causation.

IMMIGRANT DERMATOSES.

DR. J. C. WHITE, of Boston, read a paper with this title. It included an account of the affections of the skin, induced, (1) By life on shipboard; (2) Those induced after arrival, by conditions not existing previously; (3) Diseases of the skin seen more frequently in other countries than in America.

Conditions on shipboard tending to induce skin affections were, mental depression on leaving home, seasickness, filth and foul air, constipation, inability to take exercise, contact with others having contagious disease. It was not uncommon for young persons to come a week or ten days after landing with an articular, or bullous eruption. Vaccination on shipboard not infrequently left a local sore of wider area than usual, due perhaps, to depressed state of health, and the fact that the patient had not been re-vaccinated since childhood. Under the second head the causes were new agencies not existing at home, among them being mosquitoes. Under the third head, imported affections, the most common was scabies. Among others was that rare affection, melanosis lenticularis progressiva, none of the cases here, as far as he knew, being in native American stock; prurigo might also be regarded as an imported disease, and was seen scarcely elsewhere than in cities with a large foreign population, like New York and Chicago.

The relative prevalence of vegetable parasitic affections among us was likely to be largely influenced by immigration. *Tinea favosa* is more common in countries from which we receive many immigrants, than here. The same was true of tubercular affections of the skin, and he was disposed to regard lupus, scrofuloderma, scrofulous gummatum, tuberculosis verrucosa, etc., as identical affections, inoculable and auto-inoculable. Leprosy was another imported disease, coming from many sources.

In conclusion the author suggested the propriety of memorializing the national government with regard to carrying out the following measures:

(1) To cleanse all immigrants of animal parasites on landing, by treatment of person and clothing.

(2) To retain in quarantine all immigrants with other contagious diseases, including venereal affections, a sufficient time for treatment.

(3) To return to their homes all persons affected with such contagious disease as it is impracticable to treat in such manner, as leprosy, tuberculosis and advanced syphilis.

(4) To provide for efficient medical inspection at foreign ports of immigration, with the power of arresting the importation of dangerous diseases into this country.

**A CASE OF SECOND INFECTION WITH SYPHILIS, AND
A CASE OF SYPHILITIC INFECTION IN A PERSON
HEREDITARILY SYPHILITIC.**

DR. R. W. TAYLOR, of New York, gave detailed histories of the two cases which had come under his observation within a year. The first was in a sickly looking woman, aged thirty-eight, who entered Charity Hospital in January last. Eleven years ago she had syphilis, having had hard swelling of the external genitals, enlargement of the glands, eruption shortly afterward all over the body, headache at night. The second year she had rheumatoid pains, mucous patches, tubercular syphilitides; the third year, serpiginous syphilitides, etc.

She married and gave birth to two weakly children which soon died. Her husband dying, she again lapsed in virtue, and turned up in Charity Hospital in January last, completely broken down in health. There were typical miliary syphilitides scattered over nearly the entire surface. All the ganglia were markedly enlarged. There were mucous patches of the tongue and mouth, and there were evidences of alopecia. She suffered pain in the joints, worst at night. The second attack was much more severe than the first. She was improving under mercurial treatment.

The second case was one of acquired syphilis in a person hereditarily syphilitic. The woman came to him first in 1879, aged nineteen, when he treated her for destructive syphilitic sore on the face, arising from hereditary syphilis, a clear history of which was afterward given him by her mother, who acquired syphilis three months before the child's birth. The child had a rash, condylomata lata, snuffles, was weakly, etc. Five years after his patient's first visit, 1886, she returned, and had then maculae roseola and scaling syphilitides all over the body; condylomata of the genitals, mucous patches of the pharynx, etc. The infection began in the right labium, and was contracted from the husband. The glands were all enlarged; there was alopecia. She had since been cured. The author reviewed and criticized published cases which were few.

ELECTROLYSIS IN THE TREATMENT OF LUPUS VULGARIS.

DR. G. T. JACKSON, of New York, in a paper on this subject, said the advantages which electrolysis offered in the treatment of lupus vulgaris compared with other and older ones were as follows:

(1) It is comparatively painless, and there is no need of putting the patient under an anesthetic.

(2) There is not the slightest loss of blood, and thus there is no dread of a surgical operation.

(3) The patient is not kept a moment from his regular business. There is no deformity caused by the treatment. There is no after treatment or application to mar the appearance. He is also spared the discomfort of a swollen face and eyes, the ordinary attendant on the arsenical or pyrogallic acid treatment.

(4) The treatment goes to the root of the disease, to the bottom of the tubercle, with far more exactness and less damage to the surrounding skin than any other caustic or surgical method.

(5) The scar left is smooth and not unsightly.

(6) The result obtained is as good, if not better, than that by any previous method. He felt sure the

members would have cause to be pleased with the method, should they give it a trial.

PLICA.

DR. H. W. STELWAGON, of Philadelphia, showed photographs of a case which he saw a few months ago. He was not sure that plica was the right name for it. The woman (Irish) came to be treated for acne, and called his attention to a lock of hair, as thick as one's thumb, springing from the middle of the occipital region, closely matted together, and falling as low as the ankles, terminating in a brush-like end. It was not sticky; had begun to grow four years before; had no apparent cause. The rest of the hair fell over the shoulders, and was not matted. There was no filth.

THE TREATMENT OF ERYSIPELAS.

DR. C. W. ALLEN, of New York, based this paper on the results of treatment, during the past two years, of 419 cases in the hospitals on Blackwell's Island, not under his care, and 47 cases in his own practice during the same time. Of the former, 21 died; average stay, 22 days; facial erysipelas in 267. Of his own 47 cases, 24 were facial; deaths, four; average stay, over seven days. The treatment employed was various, but was principally local, consisting in applications of different kinds. Dr. Allen thought that, although tending to pursue a definite and usually favorable course, the disease could be checked in its course by treatment. Among the applications were boracic acid, iodine, resorcin, bicarbonate of sodium, ichthol, collodion, aristol, scarification with the knife, and plaster strips. He was disposed to think favorably of scarification and adhesive plaster, separately or combined in the same case; had tried them in only about two cases.

NOTES ON PILOCARPINE IN DERMATOLOGY.

DR. H. G. KLOTZ, of New York, in this paper first gave a review of the history of pilocarpine in dermatology. He said it had not met with the acceptance which one might have supposed if its therapeutic virtues had been at all proportionate to its diaphoretic qualities. The author had employed this remedy in a few cases, including some of eczema, pruritus of the anus, and affections with dryness and irritation. The result had been such as to encourage him to give it a further trial. It might be given internally or by hypodermic injection, small doses, long continued. A tenth of a grain was likely to prove sufficient to keep the skin moist.

ARISTOL.

DR. C. W. ALLEN, of New York, read a paper giving the results of his experience with this new remedy, and summed up with the statement that it seemed to possess valuable cicatrizing, granulating and stimulating qualities, was void of the objectionable odor of iodoform, and seemed valuable in certain cases.

**THE TREATMENT OF DERMATOLOGICAL CASES BY
SULPHUR WATER, AT RICHFIELD SPRINGS.**

DR. C. C. RANSOM, physician in charge of the new bathing establishment, by invitation, gave the results of treatment of dermatological cases there. Since the new bath had been completed, during the summer twenty-two cases had been treated, including nine of eczema, one of psoriasis, four of seborrhœa, one of pruritus, two of urticaria, etc. There was marked improvement in nearly all of these cases, and in some

cases a cure. The baths were of a temperature usually from 85° to 106° F., lasting from seven to fifteen minutes. A longer stay in the sulphur bath had a depressing effect lasting some hours.

The Association adopted resolutions expressing appreciation of the very extensive and complete equipment for water treatment established by Mr. Proctor at the springs.

Among those taking part in the discussions on the papers, besides the readers named, were Drs. Hardaway, of St. Louis; J. E. Graham, of Toronto; James S. Howe, of Boston.

Dr. Greenough, of Boston, was elected President; Dr. L. N. Denslow, of St. Paul, Vice-President; and Dr. G. T. Jackson, of New York, Secretary and Treasurer.

Recent Literature.

Terminologia Medica Polyglotta. A Concise International Dictionary of Medical Terms. Compiled by THOMAS MAXWELL, M.D. (Camb.), B.Sc. (Lond.), F.R.C.S., (Edin.). London: J. & A. Churchill. Paris: G. Masson. Philadelphia: P. Blakiston, Son & Co. 1890.

In this volume of 450 pages the editor has sought to meet the needs of medical men wishing to read the medical literature of other countries. For this purpose he has selected French as the key language; that is, as will be seen by the scheme on the title-page quoted above, French is the one language all of whose terms are rendered into each of the various other tongues, and the terms of every other tongue (besides whatever other language they may be rendered into) are always translated into French. For example, an Italian reading German wishes to know the meaning of the word *Leiste*. Referring to it, he finds *groin* (English) and *aïne* (French). If he does not know either of these words, he looks under the French term *aïne*, and finds its Italian synonym *inguine*. The English reader is, however, treated as well as the French; for while the latter is the key language in the sense above indicated, yet all words of every tongue are rendered also directly into English. The Spaniard and the German, however, like the Italian, may have to

employ the medium of the French to get their foreign words rendered into their own vernacular.

A single alphabetical arrangement for all languages is adopted, thus avoiding the necessity of repeating many words which differ in different languages only in their terminations; so that the 25,000 words which the dictionary contains really represent much more than that number of terms to the intelligent reader.

While all French terms are translated into Russian, a Russian-French portion has not yet been arranged for.

The great compactness and handiness of the present volume, and its serviceable and attractive binding, will contribute, with its other useful qualities, to make it a valuable book to all who attempt to follow the medical literature of other countries.

May's Diseases of Women, being a Concise and Systematic Exposition of the Theory and Practice of Gynecology, for the Use of Students and Practitioners. Second Edition. Revised by LEONARD S. RAU, M.D. Philadelphia: Lea Brothers & Co. 1890.

The second edition of this work is a distinct improvement on the first. Though only five years has elapsed since its first appearance, the science and practice of gynecology has made such rapid strides that a good many changes have been necessary. Chapter I., on Methods and Instruments of Examination, and Chapter VIII., on Diseases of the Fallopian Tubes, have been re-written. Illustrations to the number of thirty-one have been inserted, which is a marked improvement. A still larger number would, in our opinion, increase the value of the book.

— We note in a lay contemporary the following story, told at a dinner, it is said, by a prominent surgeon, at the expense of a brother practitioner who was present.

Calling the attention of all present to the young man, he said: "I have a good joke on John. He had a very bad case of pneumonia which he had treated very well. His patient pulled along nicely, and was finally nearly well. John told him so, but said that in three days he would call again to see if anything further was needed. In three days he called. His patient's brother met him at the door with a long face and said, 'I have sad news for you doctor, brother is dead.' John stood there for a minute and thought, 'Well, how am I going to get out of this. I have got to let myself down easy.' He began to run over in his mind all the causes that might produce a sudden death, and finally decided on one that he thought would do. He said, 'Such things happen now and then. Sometimes one cause and sometimes another brings it on. Now, I expect that, with your brother, a clot of blood suddenly formed in the heart and killed him.' He rattled this off, and kept talking for several minutes without giving his listener time to say a word. He stood with his mouth open, and gazed at the doctor as the latter fired technical terms at him. Finally, as John stopped to take a breath, he said in the most serious tone: 'No doctor, that ain't what killed brother. He went down to the canal and fell in and was drowned.' John did not say a word, but left, and has never had the heart to send in his bill."

THE BOSTON
Medical and Surgical Journal.

THURSDAY, SEPTEMBER 11, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
 283 WASHINGTON STREET, BOSTON, MASS.

THE PHYSICAL SYMMETRY COMPETITION AT CAMBRIDGE.

A MATTER of much interest to students of the human figure has been the award by Dr. Sargent, of the Hemenway Gymnasium of Harvard College, of certain prizes by him offered for examples of symmetrical physical development, in accordance with his tests therefor as explained by him in a series of articles during the last three or four years in *Scribner's Monthly* and elsewhere.

The principle on which Dr. Sargent bases his estimate of physical symmetry is this: A very large number of men and women are subjected to the usual series of anthropometric measurements. These data establish the physical measurements of the average man. Each measurement for any individual bears a certain relation to this average standard. For example, A's height is 70 inches. Reference to the standard shows that (say) 85 per cent. of all fell under 70 inches in height. A's height then is given a so-called "percentile" value of 85. Not that it represents that per cent. of a maximum or an ideal height, but that 85 per cent. of all measured were of that height or less, and only 15 per cent. were taller. In like manner A's percentile value for weight, height sitting, height of pubic arch, girths of chest, waist, hips, thighs, arms, and so on for a long series of measurements are determined. A chart for A is then platted, the abscissæ representing "percentile values," and the co-ordinates the various measurements taken. The former lines are so ruled that each space represents 2 1-2 per cent. except above 90 and below 10, where the lines represent 1 1-4 per cent.

It is found, for most individuals, that this chart presents a very erratic curve. Starting for a given weight, for example, at a percentile value of 70, a man's height may represent 90, while some poorly-developed part, as the upper arm, the chest or the thigh, may deflect his curve down to a percentile value of 20 or 30; or on the other hand, an overlarge abdomen may deflect it in the other direction to 90.

The ideal man or woman, according to this scheme, is one whose curve approximates a vertical line running down through all the measures at a constant percentile value, which for the average stands at 50 per cent. But for the determination of individual symmetry, it matters not at what point of percentile value the curve starts,—that is, a man may be short or tall, heavy or light,—but whatever his percentile value in one of these measurements, the same value approximately should be maintained for all the other measurements to which he is subjected; in other words, his parts must all be of uniform excellence.

Some three years ago Dr. Sargent offered quite a large sum in prizes, for physical symmetry. A first prize of \$500 each for a perfectly symmetrical man or woman, that is, for one of either sex whose line thus laid out on a chart should be a perfectly straight perpendicular, failed to discover any such, and it was therefore not awarded. A second prize of \$200 was offered for any individual whose line of symmetry showed no divergence from the vertical greater than five contiguous lines; this also failed to find a successful applicant. He has just awarded, however, two third prizes of \$100 each to the man and woman respectively, who have the most measurements within any five contiguous lines, provided none of the measurements depart more than five lines further from these lines on either side.

These prizes were offered long enough in advance for any competitor, whose deflections as shown by his chart were in measurements of girth, to correct them by systematic physical culture, so as to bring them into closer conformity with the average of his class—in other words, to straighten the curve on his chart.

The successful man in this competition is a senior in Bowdoin College, one who has been a prominent oarsman during his college career. The successful woman is also one who has given special attention to physical training as a student and teacher. It is announced, however, that the woman who came second on the list for symmetry is a saleswoman of Boston, who presumably had not had the benefit of any systematic training, but whose physical perfection was discovered by chance when she was visiting the gymnasium as a guest.

The measurements made by Dr. Sargent upon which he bases his estimate of the ideal form, must be very numerous, having now extended over some twenty years. They are mostly made from the student-class, and presumably include few representatives of any of the handicrafts. If the latter were included it is evident that the number measured must be very large, and must include all different trades, for a preponderance of any sort of handicraft would give an undue prominence in the average to some special group of muscles.

The correctness of this principle of estimating physical excellence will appeal to each individual according as he admits or not the coincidence of the ideal human form with the *average* human form, as determined by such measurements.

It would be a matter of much interest to know, for instance, how far those artistic representations, which

have always been held to be ideal specimens of bodily perfection, such as the Apollo Belvidere, the Faun of Praxiteles and the Venus of Milo, would give the "vertical line" on Dr. Sargent's charts. Whether, in other words, these specimens of ideal humanity would correspond to the averages of all measurements of actual humanity, and if not, which of the two represents the ideal of perfection.

It also naturally occurs to one that the waist measures of women, many of whom have practised tight lacing, would show even if they had no inheritance of small waists from generations of lacing mothers, an average less than the ideal, and that therefore a symmetrically-developed woman would be likely to depart at this point of her line from the curve of the average. But Dr. Sargent says that "as women are born of the same parents that have produced men, so their measurements, *en masse*, are as true to nature as men's are; and though the normal standard for women is low as compared with men's normal, and both below what they should be, in the opinion of the idealist, still we cannot help thinking that they form a more reliable standard for comparison and better models to build from than any artificially constructed normal, though it may have the lines and proportions of a paragon."

The physician will hardly admit the infallibility of "the vertical line" which Dr. Sargent claims "is the physical sign of health and longevity, of perfect structure and harmony of function," for by his charts one of Stanley's dwarfs might show an ideal symmetry, while a blacksmith by reason of his trade would show a divergence in his line of measurements from the average on the points representing the deltoid and biceps development. Yet no physician would say that in the matter of health, longevity, general usefulness and practical perfection of physical make-up, the latter might not be superior to the former.

In fact, all specialization into crafts and trades is likely to militate against the ideal symmetry which Dr. Sargent seeks. We cannot but express our admiration, however, for the ingenuity and patience with which this observer has explored this most fascinating subject, and our appreciation of the good results which may be expected to follow if persons of both sexes in the formative stage of their development can by use of these charts be aided in developing those portions of their physical structure which depart most widely from the type of their kind, and from the other portions of their own bodies.

ANTISEPSIS AND ASEPSIS IN SURGERY.

THE paper read by Lister "On the Actual State of Antiseptic Surgery" at the Tenth International Congress, was remarkable as indicating certain changes in his practice in conformity with a more extended experience in antisepsis. He states that he had given up the spray some years ago; he now considered it of value at most, only for the continuous disinfection of the operator's hands. It might easily do harm, be-

cause the motion of the air produced by it, might carry off germs with it, and convey them to the wound, not to mention that the use of the spray sometimes led to the neglect of other antiseptic precautions. He advised the leaving of complicated contusion wounds open at first, having been disappointed in the results of complete closure under antisepsis. He declared his preference for sublimate over all other antiseptics, and advised the use of dilute solutions (in some cases 1 to 10,000) to avoid irritating the wound surfaces as much as possible. In operations in the pleural cavity, drainage was necessary, as well as the antiseptic bandage.

At the recent meeting of the French Association for the Advancement of Sciences, (Session of Limoges, August 13th) Terrier, of Paris, read a communication on "Antisepsis and Asepsis in Surgery." Like Lister, he has abandoned the spray, or if he uses it at all, it is before abdominal operations, when he "pulverizes" a certain quantity of water in the operating room to facilitate the disappearance of the particles of dust contained in the air.

As antiseptic, he employs exclusively the bichloride of mercury, a 1 to 1,000 or 1 to 2,000 solution. With these solutions he washes the part that is to be the seat of the operation; his own hands and those of his assistants, after having previously been scrubbed in hot soapsuds, and the nails scraped, were washed in the same solutions. The sponges are boiled, and otherwise rendered aseptic.

For ligatures, he employs only pressed silk, boiled before each operation in a 1 to 1,000 bichloride solution.

All the instruments except the bistouries, are sterilized by dry heat, the dry stove of Poupinel being employed for this purpose; in this apparatus the instruments are kept without injury for fifteen to thirty minutes at a temperature of 160° to 180.6° C. As for the cutting instruments, they are first soaked and washed in chloroform, then boiled in sterilized water. The compresses which serve to protect the parts surrounding the field of operation, to cover coils of intestines, etc., are sterilized in the autoclave at a temperature of 120° C., according to the directions of Pasteur; before being used, if found too hot, they may be dipped into tepid water which has been boiled and thus sterilized.

Terrier says that by means of these precautions he has performed a great number of grave operations (ablation of abdominal tumors, cholecystotomies, gastrotomies, etc.) with no untoward result.

As for the dressings which he uses, they are extremely simple. He employs exclusively sterilized wadding, — not antiseptic, but prepared by heating in the dry stove, according to the method of Quenu.

MEDICAL NOTES.

— Dr. S. Weir Mitchell, of Philadelphia, is said to have recently received from a female patient the sin-

gular present of a cord of white-oak wood, chopped down and sawed up by her own hands. He had recommended to her an active out-door life in the woods for nervous invalidism. She had followed his directions, with results of which the cord of sawed wood was one of the evidences.

— Press despatches announce that Dr. Henry Muirhead, the late President of the Glasgow Philosophical Society, has bequeathed the sum of \$125,000 for the erection and endowment of a college, which shall be devoted entirely to the instruction of women in the theory and practice of medicine, surgery, dentistry, electricity and chemistry. It is said to be highly probable that some of the professional chairs, at least, will be filled by men.

— A feuilletonist, in a daily contemporary, speaks of the waiting-room of a busy doctor as usually containing one copy of a morning paper, several of last month's issue of the same paper, and half a dozen well-thumbed comic periodicals which were crisp and bright and snappy some time before the war. It is a pleasure to enter a medical man's room and find a very different arrangement. He adds that he was kept waiting lately for ten minutes in the outer office of two doctors who have a "Box and Cox" tenure of the premises. Several morning papers were on the tables and couches, and upon the walls were some excellent engravings of pictures which dealt with the more pathetic and humane side of a physician's life. There was a "Physician of the Soul," in a French picture, riding upon a donkey and hastening slowly over the snow-covered mountain at midnight. And there was the "Physician of the Body," mounted on a sturdy pony, making his way over the same mountain. The body evidently had received earlier attention than the soul. There was something in the little pictures to make one think, and perhaps to doubt, whether the moral was based upon French reverence or irony.

— The *Gazette Médicale de Strasburg*, July 1, 1890, contains the particulars of the successful operation by Dr. Schmeltz of Nice, of a complete extirpation of the mamma, performed upon a single woman aged twenty, during hypnotic anesthesia. The suggestion of painlessness lasted not only through the period of a slow and careful operation, but through the following night.

— A thunder storm is generally believed to be a bad thing for a dairy. An Italian *savant*, Professor G. Tolomei, has lately made some experiments on the relation of electricity to the souring of milk. He found that the passage of an electric current directly through the milk not only did not hasten, but actually delayed acidulation, milk so treated not becoming sour until from the sixth to the ninth day, whereas milk not so electrified became markedly acid on the third day. When, however, the surface of a quantity of milk was brought close under the two balls of a Holtz machine, the milk soon became sour, and this effect he attributes to the ozone generated.

— It has often been said that the greatest of the gifts of God which take the form of genius—I mean oratory—is the most potent of all for immediate effect, but most transitory for fame; and so it is with the sister histrionic art. The dead printed matter (all that we have left of John Bright) gives not the slightest idea of the great artist he was. The phonograph may alter all this, and the orators of the future may enthral audiences as much as the skill of Leonardo captivates you in the chapel at Milan, just as it could have done four hundred years ago. We have no such promise for the fame of the surgical artist, for he and his handiwork perish alike, leaving nothing but the bald and printed statement of cases. The limner's work lives almost for all time. We have only one comfort. In the days which Edward Bellamy predicts, and for which William Morris pines, the limner and the surgical artist will be the only highly-paid craftsmen, for their art will remain something unapproachable by mechanical contrivance. (This may be or may not, but it is a compliment of no small excellence that so great an authority ranks our craft so high.) — *Lawson Tait's Address in Surgery at the British Medical Association.*

— A young man, "a wayfarer," called not long since at the house of the German Lutheran minister in a Pennsylvania country town, and asked for supper and a place to sleep. The minister was absent. His wife gave the stranger supper, and sent him to bed. He did not complain of being sick. During the evening the clergyman returned. In the morning, as the man did not respond to the servant's call, the minister went to the stranger's room, and found him dead. A physician then being called, found that the man had died of small-pox.

— The *Medical Record* having recorded a case of tobacco smoking at four years, a correspondent lowers the record by adducing an instance of a child, who, at three years of age began smoking his mother's pipe, "and much preferred a cigar to a stick of candy." Counter-irritation of the seat of the patient is suggested as an appropriate treatment for such cases.

— An Italian correspondent writes to the *Lancet*: "An occurrence as strange as it is tragic is just reported from Sicily. At Milazzo, a seaport of that island, a barque had put in after a voyage from Genoa, having in her hold, by way of ballast, a number of wine-butts which, encrusted on their insides with tartrates, had, to give them the necessary weight, been filled with salt water. On coming into harbor these butts had to be emptied before refilling them with wine, and for that purpose one of the crew, having raised the trap-door admitting to the hold, went down to tap them and run their contents through the drain-holes into the sea. No sooner had the bungs been knocked out than forth rushed a poisonous gas, which took the man's breath away and made him fall, a corpse, into the escaping salt water. In ignorance of what had happened, a second mariner, then a third, and finally a fourth went below — each, in turn, to be asphyxiated

instantaneously, and to fall headlong into the salt water, now of some depth in the hold. As the butts continued to empty, the poisonous gas increased, and the captain, wondering that none of the four men reappeared, went, out of curiosity, to the trap-door, only to receive a tremendous rush of the gas in his face, and to fall below, asphyxiated and drowned. The cabin-boy, the sole survivor out of a crew of six, seeing what had happened, shouted widely for help to the bystanders on the quay. Assistance soon came, and the stifling fumes, by this time escaped or so diluted as to be innocuous, admitted of the newcomers looking down into the hold. There were the five men quite dead floating in the water. The corpses were hoisted up with ropes, and the medical officers, who had now arrived, pronounced them past recovery." The explanation offered as to the character of the asphyxiating gas is by no means satisfactory.

—The irreverent Bill Nye has been parodying one peculiarity of Stanley's book. In a syndicate letter he narrates his experience as "Chief of the Rear Guard of the Emen Tuteweller Relief Expedition," the object of which was to relieve Emin Tuteweller, who was lost somewhere in the jungles of Coney Island or Far Rockaway.

He writes: "We had only proceeded a little way to the westward, when one of our Wangwana was taken with violent retchings and paroxysms, caused, as I afterwards learned, by over-eating the luscious, but unripe dingle dangle fruit of the Island, which grows in great abundance to the southward, and resembles our American popcorn ball. I administered a box of large navy blue pills made by a dealer on Broadway, whose name and check I did not get in time for use in this report. These pills are about the size of a brass thimble, and I think are called the ne plus ultra, or seek no further pill. It is by far the most faithful and painstaking pill, I think, that I ever used in my African explorations. No matter how far I would go into the interior, this pill was there, like my good angel, urging me and cheering me to go still further."

NEW ENGLAND.

—Over \$25,000 have been subscribed for building the proposed hospital in Waltham, Mass.

—The trustees of the Massachusetts Hospital for Dipsomaniacs and Inebriates, have chosen Dr. Marcello Hutchinson superintendent. He is now the first assistant physician at the State Lunatic Hospital at Taunton. He will close his work there and begin his new duties as soon as possible. The work of preparing plans for the hospital buildings will be entered upon at once, the design of the board in selecting a superintendent at this time, being to have his advice and experience in the matter of construction. Dr. Hutchinson is about forty-one years of age. He was born in Wakefield, Mass., graduated at Harvard College in 1872, and at the Harvard Medical School in 1877, when he at once went to the State Lunatic

Hospital at Taunton as second assistant, and was advanced to the position of first assistant in 1885.

NEW YORK.

—The last monthly bulletin of the State Board of Health states that there were 11,083 deaths reported in the State in the month of July; which is 88 above the average for the last five years. The deaths under five years of age were 2,609 in New York and 1,384 in Brooklyn. July has, uniformly, the largest death-rate of any month in the year. For the past five years, according to the bulletin, the average number of reported deaths per month has been 7,864; while that of July has been 10,252. The infant mortality is also highest in July; more than half of the deaths being of children under five years of age, while the average of the rest of the year is about one-third. For July of this year the infant mortality is a little below the average, but is much higher than in June. A little more than 25 per cent. of all deaths are from diarrhoeal diseases; which is lower than the average by about 5 per cent. Of the 2,864 deaths from this cause, 2,393 occurred in 26 cities, having an aggregate population of 3,483,000; 285 in 106 large villages, having a population of 692,000; and the remainder in the rural parts of the State. Diphtheria is reported as prevalent at Malone, and abating in Glens Falls. The number of deaths from it is less than in June. A few deaths have been reported as due, in part, to epidemic influenza. No small-pox exists anywhere in the State. Whooping-cough is prevalent at Hudson, and has caused a considerably increased death-rate in numerous localities. Five deaths occurred during the month from lightning stroke.

—For the first time in the history of the new Capitol at Albany, the members of the legislature at the next session will sit in comfort, with safe surroundings, and in a pure and healthful atmosphere. The building is, at the present time, undergoing thorough renovation from cellar to roof, and a large force is at work in correcting the glaring sanitary defects that have hitherto existed in it. It seems ridiculous that, in a building so expensive as the Capitol, and with all the architectural talent that has been employed upon it, the question of fresh air should have been totally neglected. In a few rooms, it is true, there has been a system of putting fresh air in, but in none has there been a system of putting foul air out. In the western end imposing fresh-air shafts have been introduced, but their efficacy has been a good deal impaired, to say the least, by the fact that the windows of half a dozen water-closets have opened into them. The building is well supplied with handsome fire-places; but hitherto it has been impossible to use them, as they have all opened upon blind flues. In several instances this condition of affairs has been remedied, and the senate-chamber, which has two enormous fire-places, will in the future have a bountiful supply of fresh air. In the past it has not been unusual for twenty per cent. of the members of the assembly to suffer from the foul air

which filled their chamber, and particularly the committee-rooms. At times the stench from sewer-gas was so oppressive that members were forced to leave the place. A system of conduits and fans has now been introduced, and the commissioner having the matter in charge guarantees that in future the ventilation will be perfect.

— At a meeting of the State Commission on Lunacy, held at Albany, September 3d, the State was divided into insane-asylum districts, in accordance with the provisions of the State Care of Insane act, passed at the last session of the legislature. There was a full board present, together with the superintendents or other representatives of the Utica State Hospital, the Buffalo State Hospital, the Binghamton State Hospital, the Hudson River State Hospital, the Willard State Hospital, the Monroe County Asylum, and the St. Lawrence State Hospital. The districts proposed to take effect October 1st are as follows, each comprising from six to ten counties: Utica District, Hudson River District, Middletown District, Willard District, Binghamton District, St. Lawrence District and Buffalo District. Until such time as the State assumes full charge of the insane, the various counties will be required to pay for their own insane at the rate of \$4.25 per week for all patients kept in hospital for three years or less, and \$2.50 per week for those maintained for any period exceeding three years.

— By a mistake on the part of a student in the Male Training School for Nurses, at that institution, a typhoid-fever patient at Bellevue Hospital was recently given half a drachm of carbolic acid, which caused his death. The medicine ordered was one drachm of carbolic acid to two ounces of glycerine, of which the dose was one teaspoonful. The nurse, who had only been in the school since the 1st of June, was arrested and held in \$2,500 bail.

Miscellany.

CHOLERA IN SPAIN.

THE Department of State transmits the following despatch from the United States chargé d'affairs at Madrid, dated August 15, 1890:

“A general review of the cholera situation in Spain for the past week shows a heavy increase in new invasions and deaths over the week previous.

“It is gradually increasing both in intensity and ground covered. At present five provinces claim its presence, Valencia, Badajoz, Alicante, Toledo and Castile. Necessarily, it has followed the lines of travel, and although the Government has made noble efforts in many ways to stamp out the disease, yet refugees carry the contagion to a more or less extent, and its presence in Toledo, Llerina, and Madrid is accounted for by this cause.

“A most remarkable state of affairs existed in Arges, a small village of some 200 people near Toledo. On the first appearance of the cholera, those pecuniarily able immediately left, some fifty in all; of the bal-

ance 120 were taken with the disease, of which over 61 died, among the latter, the parish priest, the carpenter of the village, and the keeper of the cemetery, who dug the graves; the alcalde and clerk were also down with it, and stories were told of mothers unable to obtain coffins for their husbands and infants, and going through the one street of the village with the bodies on a cart to the cemetery, and obliged to dig the graves themselves. What few stores the town contained were closed. The inhabitants were actually starving to death until the Government stepped in and sent provisions, medicines, carpenters, and general assistance. The misery which existed in that little village is without parallel.

“The city of Valencia has a sanitary brigade which makes immediate visits to suspicious cases, and in one case they treated a woman who died a few hours afterwards; they ordered her immediate burial, but the woman's daughter claimed that her mother was not dead; the doctors insisted that she was, and insisted on the funeral, which took place under Government's orders. The parish priest sided with the daughter, and the result was, the next time the brigade appeared a mob congregated, and the physician and assistants were stoned and abominably assaulted. They naturally declined to do any further work in their line, and that portion of the city is unprotected, and there occurred to-day eight or nine new cases. In Madrid several deaths have occurred, which, on investigation, showed the unfortunates came from infected towns. A reappearance of the disease is also reported from Denia.

“A summary of the official reports from August 1st to August 14th, gives 1,042 new cases and 505 deaths.”

ATROPIA IN THE TREATMENT OF ENURESIS.

DR. R. BRUCE JAMES, of New York, gives us in the *Archives of Pediatrics* for September, 1890, the results of his experience in an orphan asylum with atropia given for enuresis according to the method so highly recommended by Dr. Baruch and others. He found it often effective in full doses while used, but leaving the patients no better off after its administration was stopped than before.

“In this institution all the smaller children are put to bed at 6 p. m., and made to rise three hours later, at 9 p. m., and urged to urinate.

“The following plan of treatment was instituted: a solution of atropia sulphate was made, of which one teaspoonful represented one-hundredth of grain of the drug. Of this solution, for the first night, each child had one teaspoonful at 6 and another at 9 p. m., and this to be increased by one teaspoonful every night till a controlling dose was reached for each case. None of them were benefited by less than four-hundredths of a grain at night, — that is, two-hundredths of a grain at 6 and two-hundredths of a grain at 9 p. m., — while others required as much as eight-hundredths of a grain (divided as above); one case was given as much as one-tenth of a grain at night without showing symptoms of poisoning.

“It may be stated that nothing short of the quantity that produced full physiological effects was of any avail. This point was insisted upon by Dr. Baruch in the paper referred to. After the controlling dose was

ascertained for each case, it was repeated every night for about one month, when the drug was withheld altogether. It was found that many of the cases were relieved, while others were not benefited. The latter were immediately put on their controlling dose, and an attempt made to diminish it, "to taper off," so to speak, but without much success in this, though in no case was it found necessary to increase the original controlling dose, except in one case where it lost its effects.

"Now, of the cases 'completely relieved,' the enuresis returned in all, with one exception, in periods ranging from one to six weeks. The case that was cured was a healthy boy but slightly affected. These cases were put on their controlling doses as they relapsed, and an attempt was made to 'taper off' with them also, and in some cases a considerable reduction of dose was effected.

"These cases were kept under close observation for eight months, during which time many of them would go without the drug, or on reduced doses, from one to four weeks without wetting themselves. But sooner or later the relapse would occur, and at the end of the eight months they were but little better than when treatment was started."

HEREDITARY SYPHILIS.

A CONSIDERATION of curious problems relating to hereditary syphilis, by Neumann, has lately been published in the *Jahrbuch für Kinderheilkunde*, xxx 1, 2, which is thus condensed in the *Archives of Pediatrics*, September, 1890:

"The following questions are proposed:

"(1) What will be the result if the father and mother are not syphilitic at the time of conception, the mother first becoming infected after conception?

"(2) What will be the effect of post-conceptional syphilis on the part of the mother, if the father was already syphilitic at the time of marriage?

"(3) What will be the effect of post-conceptional syphilis upon the offspring, the health of the father at the time of marriage being unknown, and the mother being well at the time of conception?

"(4) How will the offspring be infected if infection and conception occur at the same time?

"(5) How will it be with the offspring if the father or mother or both were syphilitic prior to conception?

"Another question might be added, namely, Does the post-conceptional syphilis of the mother pass to her fetus, which was healthy at the time of conception, and if so, in what month of pregnancy does the infection occur? In respect to this question Neumann disagrees with the answer of Kassowitz, that the fetus, with a healthy father, could not sustain intra-uterine infection by the post-conceptional syphilis of the mother. Kassowitz himself subsequently modified his opinion in stating that the passage of the syphilitic contagium from mother to child, and conversely, might occasionally take place, and that then the organism of the fetus, remaining free from syphilis in spite of the placental circulation, would have acquired a high degree of immunity from subsequent syphilitic infection. As to the period of time in pregnancy in which the virus passes from mother to fetus no one has yet offered any satisfactory answer. The statements of Neumann are based upon two hundred and sixty-one cases which were observed in his clinic.

Of pure post-conceptional syphilis there were eleven cases; of the eleven children, four remained free from syphilis. The infection of the four mothers in these cases took place in the ninth, seventh, sixth and fifth month (lunar) of gestation. Two of these mothers had treatment for syphilis during pregnancy; the others did not. The infection of the other mothers, who were delivered of macerated, dead, or syphilitic infants, occurred between the second and eighth lunar months, and of these, two received treatment during pregnancy.

"In a second series of fifteen cases, in which the fathers were syphilitic at the time of marriage, the mothers were not infected until pregnancy was established. Of the fifteen children of these mothers, eight were born dead, the mothers having been infected in the second and sixth months; five were born healthy, the mothers being infected between the fourth and ninth months; two were syphilitic, whose mothers were infected in the fourth and fifth months. A third series includes sixteen cases of post-conceptional syphilis, in which the conditions of health of the fathers were unknown. Of the sixteen children, three were born dead, their mothers being infected in the second and third months; five healthy, infection taking place in the sixth to eighth month; five premature, infection in the first to fifth month; one syphilitic, whose mother was infected in the fifth month; in two others the time of infection could not be ascertained.

A fourth series included thirty-nine cases in which conception and infection were simultaneous; fourteen of the infants were mature and healthy; twenty-one premature and macerated; four were born alive, but were syphilitic.

"In a fifth series of twenty-nine cases, in which the mothers were diseased prior to conception, eight children were mature and healthy at birth; three mature and syphilitic; five were premature; there were thirteen abortions, the fetuses in seven of them being macerated. The following conclusions were drawn from the entire one hundred and twelve cases:

"(1.) In pure post-conceptional syphilis, infection of the mother in the first months of pregnancy favors disease in the child, but in almost half of all the cases the children are, in fact, healthy. It is therefore certain that the barrier between mother and fetus can be traversed by the syphilitic virus, and that in the last one hundred and twenty days of pregnancy infection of the mother at least endangers the fetus.

"(2.) Even when the syphilitic disease of the father is evident at the time of marriage, and the mother is not infected until subsequently, healthy children may be brought into the world.

"(3.) In the case of post-conceptional syphilis, in which the condition of the father is not known, there is great probability that there will be many instances of purely post-conceptional syphilis in the children.

"(4.) In the cases in which conception and infection took place simultaneously, fifteen out of forty-seven children were born healthy, in spite of the assumption that under such circumstances they ought to be syphilitic.

"(5.) If infection occurs before conception, it is necessary to know how long an interval has elapsed. A long interval of time and mercurial treatment of the parents are favorable conditions for the fetus.

"(6.) The statement is incorrect that tertiary syphilis makes women sterile."

EXTIRPATION OF THE THYROID GLAND.

The London *Medical Recorder*, August 20th, condenses from the *Occidental Medical Times*, July, 1890, a case of the above operation, interesting in itself, and from its effects on the patient.

J. S. W., aged forty-two years, a clerk, entered the Southern Pacific Company's Hospital, September 17, 1888. About eight months ago he had noticed a small tumor situated in the neck, close to the right border of the trachea. This gradually increased in size, and two months ago began to cause inconvenience through pressure upon adjacent organs. On admission, he complained of considerable difficulty in swallowing, and at times the mass obstructed the respiratory act. The author accordingly at once determined upon removal of the tumor. Ether having been administered, assisted by Drs. Cluness and Gardner, he made an incision two and a half inches long over the right border of the trachea. Through this the tumor was readily exposed. At the same time it was discovered that both lobes of the thyroid were considerably hypertrophied. Although the tumor was attached to the right lobe of the gland by a rather large pedicle, it was apparent that the connection was very intimate. In view of the hypertrophy of the gland, he concluded to remove it with the tumor. This was done by extracapsular enucleation. The right and left superior and left inferior thyroid arteries were tied twice in

their continuity, and then divided. The same course was pursued in dealing with other important vessels, both venous and arterial. In this he was greatly aided by the use of a pair of curved transfixion forceps. The blunt points of this instrument having been passed around a mass of vascular tissue, were opened, and made to grasp a double ligature. By this means the entire gland was separated with a minimum of hemorrhage. The resulting cavity was provided with drainage-tubes, carefully irrigated, closed with wire sutures, and dressed antiseptically. The ligatures, which were of strong hemp-twine, came away in from five to ten days, and the wound healed without interruption. For the first few days some difficulty was experienced in breathing and swallowing, but these symptoms disappeared without untoward consequences. At the end of four months from the operation the patient seemed to present symptoms of incipient myxedema. His face was puffy, his limbs edematous to a marked extent, and his skin waxy and pale. Mental depression and inability to concentrate his mind upon his ordinary work was also noted. He complained of great weariness and lassitude, with neuralgic and muscular pains. These symptoms persisted for several months, and then under tonic treatment, gradually subsided. The patient has been seen very often during the past year, and continues to be able to pursue his calling as an accountant, though his health is naturally poor."

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 30, 1890.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 30, 1890, TO SEPTEMBER 5, 1890.

APPOINTMENT.

JEDDEHIAH H. BAXTER, Colonel, chief medical purveyor, to be general, with the rank of brigadier general, August 16, 1890, vice Moore, retired from active service. Headquarters of the Army, A. G. O., Washington, September 1, 1890.

Leave of absence for one month, to take effect September 15, 1890, is granted First Lieutenant THEODORE F. DEWITT, assistant surgeon, U. S. Army. Headquarters Department of Texas, S. O. 76, San Antonio, Texas, September 1, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 6, 1890.

J. C. WISE, surgeon. Detached from Torpedo Station and to the U. S. S. "Alliance."

PAUL FITZSIMONS, surgeon. Ordered to the Torpedo Station, Newport, R. I.

GEORGE A. BRIGHT, surgeon. Detached from the U. S. S. "Constellation" to Naval Academy.

F. W. ALCOTT, assistant surgeon. Promoted to be passed assistant surgeon, U. S. Navy.

A. R. WENTWORTH, passed assistant surgeon. Requests to withdraw resignation, granted.

M. H. CRAWFORD, passed assistant surgeon. Detached from the U. S. S. "Monongahela," and granted two months' leave of absence.

JAMES F. KEENEY, assistant surgeon. Detached from the U. S. S. "Richmond," and granted two months' leave of absence.

CHAS. H. T. LOWNDES, assistant surgeon. Detached from Naval Academy and ordered to the U. S. S. "Richmond."

RESIGNATION.

DR. SAMUEL S. DIXON, professor of hygiene and dean of the Medical Department of the University of Pennsylvania, has resigned, in order to devote all his time to bacteriological research.

DEATH.

In Danversport, Mass., September 4, 1890, Daniel Homer Batchelder, M.D., M.M.S.S., aged seventy-nine years.

Nashville, Cambridge, New Bedford and Brockton 1 each. From measles New York 8, Brooklyn 2, Chicago, Philadelphia, Franklin Park, Springfield, Worcester, New Haven, New Bedford and Charleston 3 each. Philadelphia and Baltimore 1 each. From cerebro-spinal meningitis, Chicago and Lynn 2 each. Philadelphia, Brooklyn, Boston, Washington and Lowell, 1 each. From scarlet fever, Philadelphia 3, Washington 2, New York and Chicago 1 each. From erysipelas Chicago 2, New York, Baltimore and Lowell 1 each.

OBITUARY. WINTHROP F. STEVENS, M.D., M.M.S.S.

Dr. Winthrop F. Stevens, a prominent physician of Stoneham, Mass., died September 5th, at the age of forty-two. He was the son of the late Dr. William F. Stevens, and had carried on his father's practice with great success, serving also as a medical examiner for his native town physician. He was a native of Stoneham and a graduate of Dartmouth, class of 1869, and of the Harvard Medical School, class of 1872.

OBITUARY. ROBERT A. MANWARING, M.D.

Dr. Robert A. Manwaring, one of the oldest and most respected physicians in eastern Connecticut, died in New London on Monday, aged seventy-nine. He began the practice of medicine in Ledyard, after several years removing to Norwich, and from that city to his native place, New London, where he has been in full practice for nearly forty years. His father was Christopher Manwaring, a descendant of the noted Manwaring family of England; his mother, Mary Wolcott, granddaughter of the famous Oliver Wolcott. The New London Telegraph says of Dr. Manwaring: "For more than half a century he was the leading physician of this section, his younger colleagues willingly seeking his advice and available by wisdom, experience, observation and admirable tact." He was a man of energy, but unostentatiously generous, and seemed to rejoice in giving his services where the personal satisfaction of doing a good deed was his sole reward. Notwithstanding his laborious life, he was uncommonly vigorous in mind and body, and had looked forward to many years of happy contentment in his ancestral home upon Manwaring hill, to which he had lately returned. He possessed a profound and much-needed intellect. His mind was a veritable storehouse of knowledge. He was a capital companion, entertaining raconteur, humorous and philosophical in a rare combination, and keenly appreciative of a good thing. He was a classmate of Oliver Wendell Holmes, with whom he kept up friendship, and from whom he received a touching beautiful letter upon the autocrat's eightieth birthday last year.

BOOKS AND PAMPHLETS RECEIVED.

The Relation of Eye-strain to General Medicine. By George M. Gould, M.D., Ophthalmic Surgeon to the Philadelphia Hospital. Reprint. 1890.

Essentials of Anatomy and Manual of Practical Dissection, together with the Anatomy of the Viscera. Prepared expressly for students of medicine. By Charles B. Nichols, M.D., Professor of Surgery and Clinical Medicine in the University of Michigan, etc. Third edition, revised and enlarged, based upon the last edition of Gray's Anatomy. Thirty handsome, full-page lithographic plates, in colors, and 180 fine wood-cuts. Philadelphia: W. B. Saunders. 1890.

THE TREATMENT OF DIABETES MELLITUS.¹

BY DR. L. SEEGEN, VIENNA, AUSTRIA.

AFTER a few introductory words the reader remarked that more than thirty years ago he had learned from the evidence of fourteen diabetes cases (reported at that time), that diabetes manifests itself in two forms. These can be differentiated, from the fact that in the first form sugar is excreted only if carbohydrate is taken in the food, and in the second form the excretion of sugar is entirely independent of the food taken. As a result of Pavly's investigations, the belief had prevailed up to this time, that the formation of sugar in the body was a fatal symptom.

It was thought that, in diabetes mellitus, there was developed in the living body a process of fermentation which normally appeared only after death, and which converted the liver-starch into sugar. Why this ferment in one type of the disease only acted upon the starch formed from carbohydrate, while in the other type it attacked the starch formed from albuminous compounds, the pathologist did not understand.

As a result of Seegen's work, it is now known that sugar-production is, in accordance with Bernard's theory, a normal process, and, is indeed one of the most important of the bodily functions. Seegen combined the results of his investigations into the following statements.

(a) The liver constantly produces sugar. This is proved by the fact that the liver of every living being contains 0.4–0.5 sugar, and by the fact that the blood leaving the liver (as demonstrated in more than sixty investigations) contains, without exception, more sugar than the blood when it enters the liver.

(b) Sugar is not formed from liver-starch, as Bernard believes.

Observation teaches us that the sugar-increase in the liver is most marked in the first hours after death; for the sugar increases from 0.4% to 2–3%, while the liver-starch remains unaltered in its condition. If the liver-cells retain their functions longer, with the aid of arterial blood, they are able to produce other carbohydrates as well as sugar.

(c) The materials from which sugar is formed are the albuminous and fatty compounds. In experiments where a diet composed exclusively of meat or exclusively of fat was given, as well as in experiments where starvation was carried to the point of inanition, the blood leaving the liver was always richer in sugar than the blood entering it.

(d) The amount of sugar carried into the circulation in twenty-four hours from the liver may be calculated (1) from the difference between the quantity of sugar in the afferent and that in the efferent blood (a difference amounting on the average to 0.1%), and (2) from the way in which the amounts of blood flowing through the liver in a given space of time, approximate each other.

This quantity of sugar amounts, in the case of a dog of 10 kilos., to upwards of 100 gr. in twenty-four hours, and in man (calculating the relation his blood-quantity bears to that of the dog) it amounts to 500–600 gr.

(e) The sugar formed in the liver and carried into

the blood from there, is constantly being destroyed and consumed in the tissues of the body.

If the liver be cut off from the circulation for only thirty minutes, the quantity of sugar in the blood sinks to one-third of its original amount; and Minkowski found that the sugar in the blood of geese *entirely* disappeared after the liver had been cut off from the circulation for a few hours.

(f) Sugar produced in the liver in so great an amount requires, for its production, a considerable amount of carbohydrates. Hence, it naturally results that almost the entire amount of food taken is consumed in the production of sugar.

This production is one of the most important of the bodily functions, as the sugar produced is a source of supply for heat-production and for bodily activity.

(g) Liver-starch is formed, to a great extent, from carbohydrates. Under a fat diet, the liver contains almost no starch; with a meat diet it contains 2–3%; while with a diet of sugar and dextrine it contains up to 12%.

What becomes of the liver-starch has not yet been determined experimentally. Probably it is changed to fat, and serves as a reserve material for sugar-production.

In the light of these physiological facts, experimentally proven, both forms of diabetes become far more intelligible to us.

In the one form, the sugar which is excreted is produced only from the carbohydrate ingested; we may then conclude that the liver has lost the power of making starch (glycogen) out of carbohydrate, and can no longer act upon the starch already formed. In this form of the disease the liver-cells are not capable of fully carrying out their functions.

In the other form of the disease sugar is excreted when not an atom of carbohydrate has been consumed in the food. This sugar is produced in the body. It is oxidized in the body and consumed in accomplishing the work of the body. The body of a diabetic patient has lost the ability of disposing of the sugar in the blood. That is to say, the cells of the whole body have become more or less incapable of fully converting the sugar brought to them.

It can now be understood that these two forms of diabetes have a very different significance; for in the first form, a patient may live for a long time, provided carbohydrates be denied him; but in the other form, the patient dies in a very short time.

The fact that in one case the *liver* cells, and in the other case the cells of the *whole body* are functionally incapable, we cannot at present explain. In other words, we are as yet entirely ignorant of the nature of diabetes. We know with certainty that diseases or abnormalities of the nervous system are often accompanied by diabetes, and we also know that all those conditions which have to do especially with the nervous system, for example, extreme mental depression, will readily produce the disease.

The heredity of diabetes is, at present, undisputed; and we also see frequently that diabetes alternates with psychosis in a family.

The reader alluded to the fact that he had determined experimentally, that morphia, chloroform and curare, drugs which affect the nervous system especially, diminish to a marked degree the conversion of blood-sugar.

Undoubtedly other causes are brought to bear in

¹ An abstract of a paper read in the Medical Section of the International Congress at Berlin.

the production of a case of diabetes; and the remarkable discovery of Mering and Minkowski, that an animal whose pancreas has been excised remains permanently diabetic, deserves mention in this connection.

The reader announced that he had studied upwards of one thousand cases of diabetes during the last year, and that he still believed, as he did thirty years ago, that diabetes manifests itself only in the two forms previously mentioned. The cases of the first form, as well as those of the second, vary in severity. In diabetes of the milder type, the degree of tolerance for starch varies greatly. While one case responds to the introduction of small amounts of carbohydrates, by an excretion of sugar, another case will take a far greater amount of carbohydrates with his food without excreting any sugar in the urine.

The tolerance for sugar-excretion, that is to say for abnormal sugar-production, also varies. Many cases begin to lose ground when the urine contains only a moderate amount of sugar, while others have two to three per cent. of sugar in the urine for many years, and continue to feel very well, provided they eat freely of meat and fat.

In general it proves to be true that the tolerance for sugar-excretion gradually increases, and patients who were very ill at the beginning of the disease feel very well under the same conditions later on, in spite of the fact that their urines contain considerable quantities of sugar. Those cases which cannot assimilate even the smallest quantities of carbohydrates, readily give one the impression, both from their general appearance and from all their symptoms, that they are cases of the severe type. Only when these cases are kept for a long time on an exclusively meat-diet, is one convinced that their disease is of the milder form.

Occasionally, diabetes of this milder form may become transformed into the severer kind. Seegen has noticed this especially in *youthful* cases as well as in those who through negligence or poverty, subsist upon a very insufficient diet.

Not infrequently, cases whose urine contains small amounts of sugar, come under observation. They are either very old people (generally between sixty and seventy years) or they are cases whose nervous systems have become greatly exhausted (especially well-marked neurasthenics).

Every sugar-excretion which can be demonstrated by the means at our command (and by Seegen's carbon test, 0.01% can be determined with certainty) is abnormal. A benign glycosuria does not exist. The importance of a small excretion of sugar varies greatly, however. In old people it is of very little importance, while in young and neurasthenic cases it always indicates a more serious nervous affection.

The course of diabetes varies. Cases of the milder form may keep very well if they can provide for themselves a plentiful and proper diet, and Seegen has seen cases which had remained diabetic for nearly twenty years, and which still felt comparatively well. Cases of the severer type die quickly, especially if they are youthful individuals. The fatal result occurs after from two to three years.

Recovery from diabetes, in the sense that the patient could eat starchy food recklessly, as is normally the case, without any evil effects, the reader had never seen.

In the treatment of diabetes the diet plays the most

important part. We cannot attack the real cause of the disease because we do not know it. Our task, then, is to prevent, so far as is possible, sugar-production. This can be done only in the mild form of diabetes. The diet should be regulated as follows: There should be absolute avoidance of carbohydrates, and accordingly a diet composed exclusively of fat and meat. Contani and other physicians have wished to embody this principle in its entirety in their practice, and Contani believes that he has seen a cure following a long-continued diet composed exclusively of meat. The reader has never seen so fortunate a result. Absolute meat diet, if it be long continued, has undoubtedly the advantage that it permits a certain tolerance for starch; but this tolerance is a very limited one, and a diabetic who, after a long-continued life of meat diet, allowed himself to live like a healthy person, would pay heavily for it.

Aside from its great difficulty of accomplishment, a diet composed entirely of meat has this great drawback: cases so treated quickly acquire a catarrhal gastritis and enteritis. Besides this, the less-determined patients generally break through their diet regulations and eat injurious food without stint, because the treatment is so very unpleasant and of such long duration.

The theory that diabetes can be cured has another great disadvantage connected with it. Patients from whose urine the sugar has all disappeared except a trace, consider themselves cured, and think their diet may be varied. In this way relapses occur.

The idea which Seegen follows out in treating his diabetes cases is as follows: there should be ordered for the patient such a diet as can be continued throughout a life-time, with the aid of a strong determination. A diet of meat and fat should prevail. Seegen warns you that the patient must not be allowed to eat meat and eggs in *too great quantities* for the purpose of building himself up. A diabetic patient does not need more meat than any healthy person who lives chiefly on a meat diet. But with this diet the patient should be ordered green vegetables in any quantity desired, and sour (not sweet) fruit in moderate amount. Bread is indispensable for a time, and Seegen orders 40-60 grs. per diem, but speaks most decidedly against fresh bread, because this always contains starch, and if allowed, the control of the diet (over the disease) will be lost. An exclusive meat diet is strenuously to be recommended:

(1.) If it is necessary to decide whether the disease is of the first or second form.

(2.) When wounds do not heal and when gangrene sets in or a surgical operation is necessary.

Sour (not sweet) red or white wine is allowed in any quantity, and yet it is an error to allow a diabetic patient to drink large quantities of wine with the idea of strengthening him. Beer may be allowed in moderate quantity, (that is, about half a litre).

In diabetes of the severe form abstinence from carbohydrates is important only because, as a result of such abstinence, the excretion of sugar is markedly lessened. To restrict cases of this kind to a meat diet is not indicated, for it makes little difference whether 20-30 grs. (sugar), more or less, are excreted; and the advantage gained is not equivalent to the privation endured.

Next to the diet, the use of alkaline mineral waters in diabetes mellitus is of unquestioned advantage.

(Carlsbad, Vichy and Neurnahr.) Without doubt the use of other well-known waters increases the tolerance for starch; that is to say, the patient can consume a greater quantity of carbohydrate during the use of these waters and for some time thereafter than he could before, without causing the appearance of sugar in the urine. Carlsbad exerts only a passing, symptomatic influence on cases of the severe form of diabetes. Seegen warns us not to send cases of this kind to distant watering-places, for experience teaches that railroad journeys exert a bad influence in cases of diabetes.

The reader has seldom had an opportunity of seeing any lasting benefit derived from other remedies. In children and young people he recommends the steady use of iron waters containing some arsenic. (Roncegno, Levico and Guber.) A trip to the South is of very great benefit.

MUSHROOMS AND MUSHROOM-POISONING.¹

BY EDWARD J. FORSTER, M.D., OF CHARLESTOWN.

If any apology were needed for the paper which I offer this morning, I think it will be found in the following extract from a newspaper of last summer:

TOADSTOOLS MISTAKEN FOR MUSHROOMS. — N. Y., August 13th. A sad case of fatal poisoning by eating toadstools mistaken for mushrooms, has occurred at N. Y. C., R. County, the unfortunate victim being Miss M. A. W., a highly respected lady twenty-five years of age. On Thursday last the W. family ate dinner of what they supposed were mushrooms, gathered from the fields near by. Shortly afterward four members of the family were taken ill — two of the daughters, M. and A., being seriously affected. Yesterday M. died at noon, and her sister is still very sick. An investigation revealed the fact that the supposed mushrooms were poisonous toadstools, closely resembling the former in appearance.

This is a fair sample of what I have found each year since I became interested in the study of mushrooms.

"Do you know a mushroom?" "Certainly, I have eaten them often." This answer generally refers to the canned ones, so often served with *filet de bœuf*, and which, by the way, resemble the fresh mushroom in flavor as much as hashed corned beef does a good porter-house steak. "Oh, yes! a mushroom is a kind of toadstool." Such are the replies generally given to my question.

"But do you know a mushroom when you are walking in the fields, and are you sure enough of your knowledge that you dare to take one home, cook, and eat it without fear of being poisoned?" I think not.

It is the purpose of this paper to endeavor to impart that knowledge, and warn you against those whose character is doubtful, and those which are known to be fatally poisonous.

I am quite sure that there are not many of the members who can with certainty distinguish the edible from the poisonous varieties. Some of you know the common meadow mushroom, but here your knowledge generally ends; you cannot distinguish with certainty the poisonous Amanita, the most deadly of all the fungi, one of the most common in our northern woods, as well as one of the handsomest.

If called to a case of mushroom poisoning, I am very much afraid you would treat it upon general principles, forgetting, if you ever knew, that general principles are here of little avail, and that reliance should be placed

upon an antidote which is as effectual here as when properly given in other cases of poisoning.

To help you to a knowledge of the common varieties which are edible beyond peradventure, to recognize the deadly Amanita, so that you can give it a wide berth, to treat properly a case of poisoning if you should be so unfortunate as to be called to one, will be my endeavor this morning.

From the dictionaries we derive the following definitions:

Worcester says a mushroom is a "fungous plant of the genus Agaricus. Mushrooms inhabit meadows, rocks, and masses of decaying vegetable matter, in many parts of the temperate regions of the earth. Among them a large proportion are poisonous, a few are wholesome, but, by far the greater number are unknown in regard to their action upon the human constitution. The name is, in popular use, often restricted to the edible species." And he says that "a toadstool is a mushroom."

Webster says of mushroom, "(Fr. mousseron, the white mushroom, from mouse, moss, or the same root bearing the sense of softness or nap). The common name of numerous plants of the natural order of fungi. Some of them are esculent, others poisonous. Mushrooms grow on dunghills, and in moist, rich ground, and often spring up in a short time. The term mushroom is sometimes applied to distinguish the edible fungi from the toadstools which are poisonous." Toadstool he defines, "(toad and stool). A mushroom, a plant which commonly grows in moist and rich grounds."

Such are the definitions of the dictionaries, but I think each person makes the distinction between mushrooms and toadstools, or defines the words according to his knowledge of the subject.

Thus, to the cryptogamic botanists, "mushrooms" include all fungi which have a cap and stem, and resemble the common edible mushroom of the market in their general appearance, and to such "toadstools" would be a synonymous word if they used it.

To the mycophagist who is not a botanist, all fungi that he knows to be edible are mushrooms; all others having the cap and stem, of the qualities of which he is ignorant or which he knows to be poisonous, are very likely to be called toadstools, — the commonly accepted idea being, that known edible varieties are mushrooms, all others toadstools. So it is that education in mycology increases the number of mushrooms and decreases the number of toadstools. To paraphrase an old saw,

"One man's mushroom is another man's toadstool."

As this name "toadstool" is founded upon a popular error, no one ever having seen a toad using a fungus for a stool, is it better to forego the use of the word, particularly as association of ideas plays so great a part in our likes and dislikes; for as toads are to many persons noisome and uncanny creatures, the disuse of the word will perhaps allow many, who otherwise would not, to eat of some of the most delicious of nature's products, upon which they formerly looked with suspicion if not fear, — "products of which" Mr. Julius A. Palmer truly says, "the harvest is spontaneous, it requires no seed-time and asks for no peasant's toil, . . . (a) feast, abundantly provided by nature for the poorest as well as the most epicurean."

I shall only use the term mushroom, prefixing it with edible or poisonous, as the case may be.

¹ Read before the Massachusetts Medical Society, June 11, 1890, and recommended for publication by the Society.

That some mushrooms are poisonous and even fatally so, no one can deny, but the danger from eating them when ordinary care is exercised is greatly overestimated.

Stevenson, who has written one of the best and latest works on British fungi, enumerates as growing in Great Britain, 1218 species of mushrooms, that is, fleshy fungi having a stem and cap.

We probably have a larger number in this country, where the study of mycology is yet in its infancy, and only portions of our territory have been thoroughly investigated.

Of this great number it is safe to say that the majority are harmless; very many are too small or too quickly perishable to be of use as food; many are known to be edible and only a few poisonous, although quite a number will cause distressing and alarming symptoms.

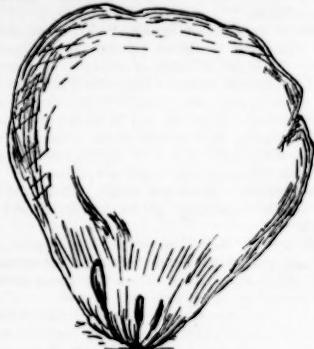

FIG. 1.

Mr. Palmer, of Boston, to whom we owe the first, and, as yet, the only series of colored plates of edible and poisonous varieties issued in this country, and who has practically and personally tested the edible qualities of mushrooms as much as any one about here, acts upon the belief that the fatally poisonous varieties will all be found belonging to a single and quite easily recognized species, namely the *Amanitas*. Many others have the same opinion, but have hardly the courage of their convictions, and back them by their practice.

Besides the mushroom proper there are many others of the fungi which are edible and easily recognized; namely, the puff balls, the clavarias, and the fistulina hepatica. There are still others, including the Morels, of which I shall not have time to speak.

The Puff-Balls (Fig. 1) are very easily recognized, being round, and when ripe emitting their spores in the form of dust. These are good when fresh, before the inside has changed from the purest white; they can be sliced, cooked in batter, and are then delicious. These are called the omelette mushroom, on account of the resemblance in taste to that dish. When eaten in proper condition, none are poisonous, although with some a slight cathartic action is produced.

The Clavarias (Fig. 2) are quite common in woods, and are readily known; they resemble a piece of branching coral in miniature. Stewed or cooked with butter, they make a good addition to any joint.

The *Fistulina Hepatica* (Fig. 3), also known as the beefsteak mushroom, can hardly be mistaken. It is red in color; in shape it looks like a tongue, and grows on oak and chestnut trees. It is not common. Professor Farlow tells me that he found several last year, and doubted if I should know the difference from a beefsteak if I had eaten them after they had been cooked. I never found them until last season, and then they were too small for me to test their edible qualities.

FIG. 2.

A mushroom we will understand to be a fungus that has a stem and cap, that is, umbrella-like in shape, and is not woody in texture.

Before proceeding further in this necessarily somewhat cursory glance at our subject, it is best that we learn the meaning of a few botanical terms.

The cap or pileus is the expanded top, and rests upon the stem. The under side of this cap bears either gills, tubes or teeth. The gills are thin plates radiating from the centre, where the stem is joined to the cap. The tubes or pores are small holes, and give the under side a spongy appearance. The teeth are spines or bristles of different lengths. All these, gills, tubes and teeth, are covered by a thin membrane, which again is covered with the spores, which are the reproductive bodies, and appear like fine dust when deposited upon anything lying under the cap. It has been estimated that the number of spores in a single plant may exceed 10,000,000. Before the cap of the mushroom is fully expanded, the under side is covered by a membrane known as the veil; a portion of this is sometimes left upon the stem, and it then forms the annulus or ring; often this is movable. With some varieties the entire plant, before issuing from the ground, is enclosed in a membrane, portions of which remaining upon the cap, form warts, and a part remains about the base of the stem, forming a sheath or volva. This is very important, as the presence of

these warts, and the volva is a guide to distinguish the deadly poisonous varieties.

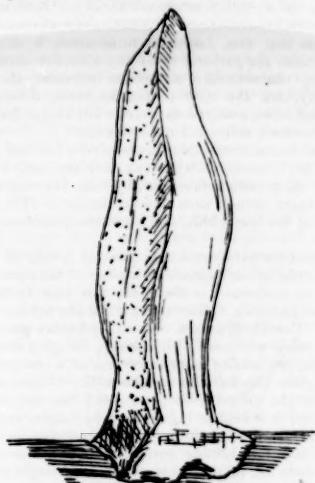

FIG. 3. *Fistulina*

Let us take up the first mushroom we find; we turn it over and see that the under side of the cap has teeth or spines; it therefore belongs to the genus *Hydnium* (Fig. 4). There are no poisonous species, but on account of the toughness and woody character of many, Dr. Badham says, "to eat must depend upon the united consent of the stomach and the teeth." The esculent variety is the *Hydnium repandum*, orange in color, two to five inches across, flesh white, turning yellow when cut, spines pale yellow.

FIG. 4.

There is no fungus with which this one is likely to be confounded; once seen, it is always remembered and may be gathered fearlessly.

We next find a mushroom with a spongy look underneath; this appearance is due to myriads of fine tubes; this satisfies us it is a *Boletus* (Fig. 5), a family which contains no members which are fatally poisonous. Vittadini says this "is not strictly the case, though many species hitherto reputed unwholesome, or worse, appear to lose their bad qualities by drying." Those having high-colored or red tubes have been considered poisonous, but no fatality is recorded. The mild-colored ones, with white, yellow or green tubes, if pleasant to the taste, are safe to eat, and sliced and fried in batter make a fair addition to our table.

FIG. 5.

This time our mushroom has neither teeth nor spines nor tubes, but has the radiating gills (Fig. 6); we are approaching dangerous ground, for among these are many whose poison is fatal.

FIG. 6.

There is no rule by which the good can be distinguished from the bad; this should be strongly impressed on the mind. That the skin of the cap peels readily, that they change color when cut or are bruised, that they do not tarnish gold or silver with which they are boiled, that the stem comes readily out of the cap or grows at one side, and a dozen other reasons, are all equally fallacious; there is no such rule which has not its exception, and here an exception may mean death. Safety lies in knowledge,—positive knowledge. You should know positively the variety or

varieties you venture to eat, and eschew all others. You should fix firmly in your mind the characteristics of those you venture to eat, so firmly that you can pick them from a basketful of all kinds. You know the difference between a squash and a pumpkin, and would make no mistake in taking one for the other; but it might puzzle you to describe the salient points so that your cook, who had seen neither, would choose by your direction from the kitchen garden the proper vegetable for an old-fashioned pumpkin pie, and not bring a squash, or possibly a bitter gourd. So it is with a mushroom,—you must know it, and know it positively; when once learned there should be no more chance for a mistake, than you would have in picking out a pumpkin.

The gill-bearing mushrooms belong to the family known as the Agaracini or Agarics; this is again divided into thirty or more genera, a division which concerns the botanist, but to us is of no value. A division which is of practical use to us is one made by noticing the color of the spores; this can be seen by an examination of the gills with a lens, or better by removing the stem, placing the cap, gill downwards, on a piece of glass, and letting it remain over night, although in some cases an hour or so will answer. The spores will be found deposited on the glass, and will show the radiation of the gills. When several mushrooms grow together and overlap one another, the spores are often found on the caps of the under ones.

Classifying the Agarics by the color of the spores, we have the following divisions :

- I. Leucospori, or white spored agarics.
- II. Hyporhodii, or pink spored agarics.
- III. Dermini, or brown spored agarics.
- IV. Pratelle, or purple spored agarics.
- V. Coprinarii, or black spored agarics.

Among the Leucospori, besides many others of which I shall not speak, will be found the following genera : *Agaricus*, *Lactarius*, *Russula*, *Cantharellus* and *Marasmius*, which contain both edible and poisonous species. The larger forms of these genera are rather easy of identification. *Agaricus* has three sub-genera which particularly demand our attention, namely, *Amanita*, *Lepiota* and *Pleurotus*.

The *Amanita* are distinguished from all others in having warts upon the upper surface of the cap, a volva and usually a ring. While some varieties are edible and much sought for, others are highly poisonous. These are the handsomest of our mushrooms, and are oftenest eaten by careless gatherers.

Notwithstanding the good character some varieties are given, a wise caution should prevent any but the experienced mycologists from essaying their edible qualities.

The *Lepiota* have one variety which can be mistaken for nothing else, the *lepiota procerus* or *parasol mushroom*. It is found in lawns and open fields, grows to an enormous size, has a long stem and is easily recognized by the brownish scaly top, the ring which is movable, and the absence of a volva. The scaly top differs from the warty top of the *amanita*; the warts can easily be removed, not so the scales which are simply the cap itself ruffed up. *Pleurotus* has one variety easily recognized; it is found only growing upon the elm tree and is edible, but to my taste of poor flavor.

Lactarius is a genus known by the milky juice which

exudes from the gills and from the cap and stem when broken. *Lactarius deliciosus*, or the orange milk mushroom, is a highly esteemed variety. Badham says "there is but one fungus which it in any way resembles, and as that one, *Lactarius torminosus* is acrid and poisonous, the gatherer must pay attention to the following characteristic difference between the two, namely, that the milk of the *Lactarius deliciosus* is red and subsequently turns green, while that of *Lactarius torminosus* is white and unchangeable."

The *Russula* resemble very much the *Lactarii* except that they have no milky juice; they are easily remembered when once pointed out, by their extreme brittleness, stout spongy stem and dry texture. They have some of the best edible, and also some poisonous varieties.

If you are sure you have a *Russula* it may be eaten, if, on trial of each specimen, a piece of the stem is not acrid or unpleasant to the taste; this rule holds good for the *Lactarii*. These two genera are destitute of a ring. *Cantharellus* is a very easily known genus, the stem being confluent with the cap, the gills thick and swollen, resembling more the veins of a leaf than the usual gills. *Cantharellus cibarius* or the "Chanterelle" is a bright yellow throughout, and has the odor of apricots; it is held in high esteem by fungus eaters.

While all the foregoing white-spored mushrooms are fleshy and soon become putrescent, *Marasmius* differs from them all, in that they wither in drought and revive when wet; they can be dried, and will keep for years, retaining all their good qualities, and when moistened they swell to their original size and are then ready for cooking. We have a very common variety which is esculent and easily recognized, namely, the *Marasmius Oreades* or *Fairy Ring Champignon*, also called the *Scotch Bonnet*. Its little buff head is seen on every lawn. It grows in segments of a circle, giving it its name of *Fairy Ring*. When once seen and carefully studied it should be mistaken for nothing else, although it is sometimes accompanied by those of about the same size, whose only resemblance is the buff color of the cap.

We have now glanced rather hastily at the white-spored mushrooms. But while many are most excellent, many are so poisonous that my advice to the novice is to wait until he becomes a student of mycology, before eating any except the *Parasol*, the little *Scotch Bonnet* and the *Elm Tree Mushroom*, and then the chance of any mistake will be reduced to a minimum. I am confident that all fatal cases of poisoning have been caused by eating those with white gills and spores; this I think is shown by the tables of cases which I have collected. Among the pink and brown spored agarics, are some which are edible, but their qualities had best be tested only by the professed mycophagist. The purple-spored agarics give us the two varieties which are so well known throughout the world and so highly esteemed for their edible qualities, namely, the *Agaricus campestris* or *Meadow Mushroom* and the *Agaricus arvensis* or *Horse Mushroom*. These so closely resemble one another that they are sold indiscriminately, and for the purpose we have in view they may be treated as one and the same. They are found in meadows, never in woods, their gills are of the most delicate flesh pink when they first appear above the ground, changing soon to a darker shade, finally becoming a dark purple almost black. The cap is dry, silky or downy, globular, with the margin

united to the stem by the veil which soon becomes a ring about the stem; when the cap expands, the latter being bell-shaped at first, and then almost flat. The stem is nearly solid, separates easily from the cap, and there is no volva.

It must be remembered that the volva is only found in the Amanita of the white spored, and the Volvaria of the pink-spored varieties, which latter we have not considered. The Pink Gill is the only species which is successfully propagated by man; vast quantities are raised in the caves about Paris; the young ones, that is, with cap unexpanded, are the button mushrooms of commerce. Many are raised by the market gardeners about Boston.

It is believed by many that the Pink Gill is never found except where cattle have been pastured, or the grass fertilized by their manure, the passage of the spores through their alimentary canal being in some way necessary for fertilization.

The Horse Mushroom sometimes grows to an enormous size; a specimen has been reported weighing fourteen pounds. These two, Pink Gill and the Horse Mushroom, are the only ones of the purple spored which had better be essayed, as other varieties are reported as causing symptoms affecting the nervous system. Of the black spored only those whose gills deliquesce into an inky fluid are considered as edible; of these there are several varieties; to one only shall I call your attention; it is so common and its characteristics so well known that a mistake seems incredible. I refer to the Coprinus comatus, or Shaggy Mane Mushroom, known also as the agaric of civilization, as it is found on dumps, dust heaps, and about lawns on newly-filled land. The cap or pileus is first oval and hard, the margin soon separates from the stem, leaving a ring, the margin quickly turns to a bluish black, and after expanding the whole plant dissolves into an inky fluid. The color is white to a brownish tint, the cap woolly or shaggy, caused by the skin peeling and curling up in small sections; the stem is hollow. This used to grow, and perhaps does now, in profusion in the grounds of the Massachusetts General Hospital. I have found it in various parts of the city. It is used in all stages to make ketchup, but to stew or broil it should be taken before it begins to turn black.

The only mushrooms of the agaric family which I think you are safe in trying, are the Parasol, Elm Tree and Fairy Ring of the white spored; the Pink Gill of the purple spored; the Shaggy Mane of the black spored. But first be sure of your knowledge.

These five varieties of agarics, with the mild colored Boleti, the spiny Hydnus, the Puff Balls and the Clavarias, will give you sufficient variety of fungoid esculents, until such time as you become a student of mycology and a professed mycophagist.

Let us recapitulate by looking at the figures and the following tables:

TABLE NO. 1.

Not Umbrella Form . . .	Puff Balls. Clavarias. Fistulina. Spines or Teeth = Hydnus.	Edible.
Umbrella Form . . .	Tubes or Fores = Boleti. Gills = Agaricini.	

TABLE NO. 2.

Agaricini.	Lemnospori, or white spored Agarics (see Table No. 3.)
	Hyperodii, or pink " " " not considered.
Dermini, or brown " " "	
Pratilini, or purple " " "	The Pink Gill.
Coprinarii, or black " " "	The Shaggy Mane.

TABLE NO. 3.

White Spores . . .	Agaricus. Lepiota — The Parasol. Lactarius. Pleurotus — The Elm Tree. Russula. Eaten on taste. Cantharellus. — The Chantereille. Marasmius. — The Fairy King.
--------------------	---

TABLE NO. 4 (Edible).

Without Gills . . .	Puff Balls. Clavarias. Fistulina. Hydnus Repandum.
With Gills . . .	(The Parasol (lepiota procerus). The Elm Tree (pleurotus ulmarinus). The Fairy Ring (marasmius oreocreas). The Pink Gill (agaricus campestris). The Shaggy Mane (coprinus comatus).

White spores.
Purple spores.
Black spores.

TABLE NO. 5.

The deadly poisonous AMANITA has	white gills, white spores, warts on cap, a ring, a VOLVA.
----------------------------------	---

The poisons of mushrooms may be as varied as the species from which they are derived, but the symptoms arising therefrom can be classified under two heads: (a) those which occur soon after ingestion, within an hour or so, and (b) those whose appearance is retarded for eight to twelve hours. The early symptoms are those of an irritant to the alimentary canal, as vomiting, purging and the consequent exhaustion; and unless the quantity taken was excessive, or the taker debilitated, the after effects would not be serious, or at least not fatal; not so, however, if the symptoms come on later; here we have the effects of an irritant narcotic, purging and vomiting are followed by giddiness, vertigo, precordial distress, labored respiration, contracted pupils, coma and death — the latter having occurred as early as thirty-six hours after the fatal repast. Most authorities agree that these more serious symptoms are only caused by the Amanitas, which you will remember as among those having white gills and spores. Some go so far as to state that it is only from these that fatal results have occurred.

To satisfy myself about this, I examined the literature of the subject, as found in the medical journals of this country, and have tabulated all the cases I could find recorded.

For ten years Mr. Palmer gave much time and study to mycophagy, and the results of his investigations he kindly placed at my disposal. He collected thirty-three cases, twenty-one of which were fatal. From other sources, — American medical journals, brother practitioners and the daily press, — I have forty-four cases, of which fourteen were fatal.

The tables are very unsatisfactory from their incompleteness, but are of value as bringing together, besides those collected by Mr. Palmer and the writer, all the cases occurring in this country which have been reported in the medical journals as noticed in the Index Medicus. Very many essential details are entirely omitted. By thus grouping the cases, the attention of practitioners will be called to these omissions, and future reports will perhaps be more carefully made. The headings used are believed to cover all important points. They are:

- (1) Number of case.
- (2) Name.
- (3) Date.
- (4) How cooked.

- (5) Description of plant.
- (6) Hour when eaten.
- (7) Taste.
- (8) Quantity eaten.
- (9) Symptoms began.
- (10) Description of first symptoms.
- (11) Description of later symptoms.
- (12) Treatment.
- (13) Result.
- (14) Length of illness.
- (15) Physician in attendance.

The writer will gratefully acknowledge reports of cases or references to the subject.

I will not detain you by reading the dry details of the tables I have prepared, but simply state that from my examination of the cases collected, I am confident that the fatal ones were due to eating such as had white gills, or had other characteristics of, or were known to be *Amanitas*. As the cases are mostly reported by those not versed in fungology, the descriptions are necessarily defective, but the mere statement that the under side of the mushroom was white, leads me to infer that the fatal result was due to an *Amanita*, writers so generally agreeing that death is not caused by other varieties.

From a study of the cases where the symptoms developed after eight or twelve hours, and more than a very small amount of the fungus had been taken, the treatment by the usual methods of giving emetics, cathartics, astringents or stimulants, combined or alone, has, I find, been universally unsuccessful; but when the chief reliance has been placed upon atropia, the results have been most brilliant. It is true that I have the records of fatal cases where this drug had been given, but in such small doses ($\frac{1}{10}$ to $\frac{1}{20}$ grain), that I was not surprised at the result.

The symptoms indicate a poison whose action is like that of morphia, and if it is to be combated successfully, the same treatment as used for an overdose of that drug must be given, namely, atropia in full doses, one-third of a grain at a time, for instance. One grain of atropia has been given in opium poisoning with success. I have treated at the Boston City Hospital, and reported a case of poisoning by morphia, where I gave three-fourths of a grain of atropia, — one-half grain at once, and one-quarter grain in ten minutes, — and saved the patient. Wharton and Stillé state that while one-sixth grain of atropia has caused alarming symptoms, death has not been caused by a grain; therefore, I think that when we have present as powerful a poison as that found in the mushroom, we had best use the antidote in moderately large doses.

The treatment by atropia is based upon the perfect antagonism which exists between this drug and the poison of the *Amanitas*, which has been separated by Professor Schmiedelberg, and named muscarin. The poison has been separated by others and variously named, according to the variety from which it was obtained. The merest trace of this alkaloid will arrest the pulsation of a frog's heart; and even after four hours Lauder Brunton states he has caused it to pulsate again by a minute quantity of atropia being brought in contact with the organ. This and other experiments showing the antagonism between these two poisons have been repeated by Prof. H. P. Bowditch at the Harvard Medical School. It acts as well upon mammals as upon frogs. My friend, Dr. F. H.

Williams, Assistant Professor of Therapeutics, tells me that he has recently brought the subject of mushroom poisoning and its proper treatment to the attention of his students in the Harvard Medical School.

In the treatment of such cases, general principles should only guide us to remove any of the poison remaining in the alimentary canal, by emetics and purgatives, to support the failing powers by proper stimulation. But the treatment should not stop here; our reliance must be upon an antidote; the poison already absorbed must be counteracted, an antidote must be used; and that antidote, I repeat, is atropia.

The course of treatment which has usually been followed in severe cases of mushroom poisoning, has been as efficacious and successful, and based upon as scientific principles, as the answer to the statement said to have been made by a southern professor, who lecturing upon tannic acid, remarked: "And by the by, gentlemen, tannic acid is the antidote to the poison of the mushroom; can any of you explain its action?"

"T-t-think I can, professor."

"Well, sir, explain to the class the chemical reactions that occur, and how tannin acts as an antidote to the poison of the poisonous mushroom."

"It f-f-forms the t-t-tannate of mush, and leaves room in the stomach!"

THE TREATMENT OF COLD ABSCESSES WITHOUT DRAINAGE: WITH REPORT OF CASES.

BY ROBERT W. LOVETT, M.D.

THE accepted methods of treating cold abscesses fall under three headings: (a) expectancy; (b) aspiration methods; (c) free incision and drainage.

The object of the present paper is to call attention to the possibility of doing away with drainage in many cases, and thereby shortening the time of healing.

The merits of expectancy against operative interference in cold abscesses have been discussed at length,¹ and the question is still unsettled in the minds of many. The tendency of modern surgery is, however, distinctly in the direction of more extended operative interference, and, except in the mind of the pure orthopedist, pus in a cold abscess is to be treated as pus is elsewhere in the body.

Methods of treatment by aspiration, with or without the injection of some germicidal solution, have been advocated by many writers, especially of late years, where many cures of abscess have been reported after the withdrawal of the pus and the injection of an iodoform emulsion or a solution of iodoform in ether. Apart from the danger of the injection into closed cavities of iodoform or corrosive sublimate solutions, the method is, in most cases, unsatisfactory, on account of the formation of more pus at the same site. The pyogenic membrane being left as the lining of the cavity, it is not surprising that the pus should form again so rapidly and so persistently.

The objection to the operative treatment of cold abscesses (an objection which pertains equally to the expectant method) lies in the failure of the wound to close, and in the persistence of sinuses at the seat of operation for months, and perhaps years. In forty-

¹ Transactions of the American Orthopedic Association, vol. II, p. 82.
New York Medical Journal, March 2, 1889.

three cases of abscess of the hip operated on at the Children's Hospital,² between 1884 and 1888, only one case is recorded as having healed within six months of operation, and about half of the sinuses healed within periods varying from one to two years, the rest remaining open almost indefinitely. These cases were all thoroughly cleaned out after a free incision, and were either packed with gauze, or, more commonly, drainage-tubes were inserted, and an antiseptic dressing applied. In the writer's personal experience the site of the drainage-tube was almost always the site of a sinus which persisted for a varying period of time.

The possibility of securing primary union even after so severe an operation as excision of the hip, has been claimed by Mr. Barker and Mr. Pollard; and a number of cases have been reported by them where it occurred.³ Drainage-tubes were not employed in any of these cases, and certain conditions were carefully observed. These were: removal of the diseased tissues, perfect asepsis, dryness of the wound, and light compression. Mr. Wright, of Manchester (who always had used drainage-tubes), in 140 cases of excision, which he had done at that time, had never seen a case of primary union. It would seem fair to conclude from the cases of hip-abscess opened at the Children's Hospital, as mentioned above, and from the excision-cases of Mr. Wright, that the use of a drainage-tube in these cases was likely to prevent primary union.

It is hardly necessary to point out the great discomfort that results from a sinus left at the seat of operation, and the decided advantage in avoiding it, if possible, by legitimate means.

To avoid, if possible, the sinus which the drainage-tube seemed always to leave after the rest of the wound was healed, the writer removed, in several instances, the tubes at the end of twenty-four to thirty-six hours after operation, but after the rest of the wound had closed, the hole left by the tube was still open to granulate, and generally continued for a long time as a sinus. The amount of discharge from abscesses which had been properly cleaned out was at first very small, and in many cases no pus appeared so long as an antiseptic dressing was continued on the wound; nevertheless, the sinuses continued to discharge serum, and when an open dressing was applied it turned to pus. The experiment was then tried of cleaning out the abscesses with especial care, and dressing them without the use of drainage-tubes, allowing the dressing to stay in place for two or three weeks. This seemed a decided improvement, as Case I will show.

CASE I. Katie M., ten years old; hip disease, acute. The child had been for some months under treatment by a traction splint; but the home surroundings were bad, and in April, 1890, a large abscess developed. May 10, 1890, the child was admitted to the House of the Good Samaritan, and a large abscess cavity was incised, which was found to extend anteriorly and laterally in all directions, and to contain about eight ounces of pus. Three incisions were necessary to reach it thoroughly. Carious spots were found on the pelvis, and the cavity communicated with the joint. The cavity was curetted, irrigated with 1 to 1,000 corrosive solution, then thoroughly dried, and dressed with corrosive gauze without drainage or packing. Light compression was

applied. The dressing was left undisturbed for two weeks, and at its removal no pus was found, but granulating patches were left at the seat of each incision where the edges were not in apposition; they were, however, superficial, and in two weeks the smaller ones were covered over, and the largest one, from an incision two inches long, was soundly healed in six weeks. The wound was firm, and the cicatrix is at present free from induration and healthy.

Similar cases operated on there, and at the Children's Hospital, and treated in the same way, yielded similar results, and much seemed to be gained by the permanent dressing. There was, however, always a patch of granulations where the edges of the incision were not in contact, and this at times degenerated into a sinus, but in most cases it was a superficial granulating patch, and not a granulating sinus, as in cases where a tube was used.

The following cases show the gain that was made by sewing up the incision so as to provide for the apposition of the edges of the wound:

CASE II. Bebbie G., eight years old; acute hip disease. The disease had been of two and one-half years' duration, and of average severity. In the spring of 1890, an abscess appeared on the anterior surface of the thigh, which increased until it was the size of a half orange. The child was admitted to the Children's Hospital, and the abscess was opened, May 13th, by an incision three inches long. Several ounces of pus were evacuated, and a sinus was found running into the joint. The pyrogenic membrane was removed by the curette in all accessible parts of the cavity, and the wound thoroughly irrigated with a 1-1,000 corrosive solution. Bleeding was allowed to stop, and the walls of the cavity were carefully wiped dry. Iodoform powder was blown in, and the wound was tightly sewed up with cat-gut and dressed with sterilized pads wrung out in a solution of corrosive sublimate 1-5,000. There was no rise of temperature, and eight days after operation the dressing was removed, and the wound was found healed by first intention throughout. The cicatrix has remained perfectly firm and soft, and there has been no accumulation of serum or pus.

CASE III. Catherine M., nine years old; hip disease, chronic. An abscess back of the trochanter was opened, and four ounces of pus evacuated. It communicated freely with the joint. The cavity was treated as in Case II, and the incision sewed up without drainage. At the end of eight days the dressing was removed, and union by first intention was found.

CASE IV. John G., eleven years old; hip disease. A large abscess on the outer aspect of the thigh was opened, and joint communication was established. The wound was treated as in the others, and tightly sewed up. At the end of twelve days complete union was found to have occurred. In these cases there was no rise of temperature whatever, and the progress of the patient was in every way satisfactory.

It would seem, therefore, that in many cases of cold abscess connected with bone disease, where from the nature of the case it is not possible to obliterate the whole abscess cavity or to exterminate the focus of disease, it is worth while to attempt to obtain primary union by careful cleansing and drying of the wound, and by its closure either by suture or by light compression, and by the application of a permanent dressing. With the use of drainage-tubes it is quite cer-

² Transactions of the American Orthopedic Association, vol. II.
³ British Medical Journal, December 15, 1888, p. 1177.

tain that a sinus will persist, as evidenced by the cases already quoted from the Children's Hospital series, and by the excision cases spoken of by Mr. Wright.

If union can be obtained in a week or two a very great gain has been made, and in properly selected cases it can hardly add to the risk.

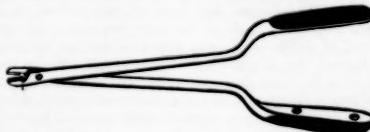

The cases reported by the writer were large, cold abscesses of average severity, connected with diseased bone during the acute stages of the disease. Abscesses of a very acute character, with much surrounding infiltration, would be manifestly unsuitable for such closure.

New Instruments.

ANOTHER NEEDLE FORCEPS.

BY W. L. BURRAGE, M.D.

THE accompanying cut represents my modification of the Baché-Emmet needle forceps, which, in turn, was a modification of the old Sims instrument.

The changes I have introduced have been: first, to shorten the jaws; second, to remodel them after the pattern of the forceps now in use at the Women's Hospital in New York; and third, to strengthen the shanks.

By shortening the jaws, greater leverage is obtained. By making the holding portion a narrow and roughened surface of steel opposed to a corresponding copper plate, the operator is much surer to catch his needle and less likely to break it, than with the former instrument having jaws with cup-shaped ends. By strengthening the shanks the holding power is increased.

In using the holder the operator separates the jaws, either by inserting his forefinger between the bends of the shanks or by allowing one of the handles to drop away by its own weight.

The advantages of this form of needle forceps are its simplicity, and its almost unlimited holding power; for it is so constructed that the handles cannot be made to touch, consequently the tighter they are grasped the more secure the hold on the needle.

The instrument is made by Codman and Shurtleff of Boston.

— The regular Paris correspondent of the *Medical Press* (September 3d) makes the very curious statement that when twins are born in France, the last born is considered by law to be the eldest! Consequently, if both survive, and, in the case of boys, reach manhood, the second is called to the army to serve, being pronounced the eldest. By some extraordinary calculation the medical men who were consulted at the passing of the Act, years ago, came to the conclusion that the last born of twins was always the first conceived.

Reports of Societies.

THE NEW YORK ACADEMY OF MEDICINE. SECTION ON ORTHOPEDIC SURGERY.

STATED Meeting April 18, 1890, V. P. GIBNEY, M.D., Chairman.

HEMATOMA OF THE STERNO-CLEIDO MASTOID MUSCLE.

DR. A. B. JUDSON presented a patient, four and a half weeks old, who had been referred to him as a case of congenital torticollis. There was a long, fusiform tumor in the course of the muscle, the hardness of which suggested a short and fibrous sterno-cleido mastoid. There was, however, but little shortening, and no wry-neck. The condition was supposed to be the result of injury to the muscle in parturition. Dr. B. E. Hadra, of Texas, had reported two cases which had been relieved by tenotomy, and Dr. F. D. Brooks of New Hampshire, had followed with a report of three cases, which had recovered by expectant treatment, or the use of friction and local applications. In the present case, a favorable prognosis had been given without special treatment.

A NEW BED FOR USE IN HIP DISEASE.

DR. A. M. PHELPS presented a little girl with hip disease, who had been treated on an improved surgical bed, which was also exhibited to the Section. When she came under his care, there was flexion nearly to a right angle, adduction, sinuses and an abscess, and the liver was already enlarged. His improved bed consisted of the ordinary iron bedstead found in hospitals, to which was added a convenient arrangement for the application of traction. The iron bed-posts at the foot of the bed was continued upwards much higher than those at the head. An iron cross-bar slid up and down on these foot-posts, and could be fastened at any height, so as to make traction at any angle desired. This cross-bar carried a pulley, which could be adjusted laterally so as to make traction directly in the line of deformity. The side-bar of the bedstead was also fitted with an adjustable pulley for the purpose of making lateral traction. This apparatus cost about five dollars, and could be supplied by Reynders, either with, or without the bedstead.

The patient whom he exhibited, had been treated by traction in this bed; but this was not sufficient to overcome the deformity. Under chloroform, the tensor vagine femoris and fascia lata, the adductors longus and magnus, and the contracted anterior border of the glutei muscles and the rectus femoris, were divided. Traction with a weight of eight pounds was then applied in the line of the deformity, and a force of two pounds at right angles to this. After two months, the deformity had been for the most part reduced, and his splint, with crutches and a high shoe, was then applied to prevent a relapse, and they would be continued until the case was cured.

DR. R. H. SAYRE presented

A CASE OF CONGENITAL LOCK-JAW.

No definite history could be obtained concerning this boy, except that he was five years of age, and that nothing unusual had been noticed about the jaw until a short time ago. The boy was quite intelligent, and no other joints were affected. The jaw appeared to be subluxated backwards, and the deformity was pre-

sumably congenital. The recession of the jaw, and the apparent atrophy on both sides, added to the interest of the case. Dr. Sayre said that before adopting any operative measures, he would attempt to relieve the case by stretching; and for this purpose, would employ a wedge-shaped instrument devised by Dr. L. W. Hubbard, and presented last year before the Society of the Alumni of Bellevue Hospital. It consisted of two plates of steel, fastened together by a separable hinge, and capable of being separated at the other end by turning a screw. Having partly separated the jaws of the instrument, a cork could be inserted between the plates, near the hinge, and the action of the screw reversed, when the instrument would exert considerable pressure on the molar teeth.

Dr. W. R. TOWNSEND presented two cases of

RACHITIC POSTERIOR CURVATURE OF TIBIA.

He said that the dispensary records showed that about two years ago, there was a well-marked knock-knee and rachitis in one case, who returned last week with the present peculiar condition of the tibia. Since then, the other case, with a similar deformity, had come under observation. The latter case presented an increased growth of one portion of the tibia, amounting almost to an exostosis. It also showed a well-marked "rachitic rosary." MacEwen had called especial attention to these secondary bone formations on the inner side of the knee in cases of knock-knee. The posterior curves of the tibia were rarely seen, these being the only cases met with during the past two years at the Hospital for Ruptured and Crippled.

DR. S. KETCH reported a case of

RHEUMATIC (?) ARTHRITIS OF KNEE.

On July 3, 1888, he was asked to see the following case in consultation with Drs. Lawrence Johnson and N. J. Hepburn:

E. S.; single; twenty-two years of age: having a good family history, had been perfectly well up to the present illness, and denied having had any venereal disease; an examination of the urethra failed to show the presence of a urethritis. Early in May, 1888, he had a slight attack of what was considered to be rheumatism in the left elbow and right thumb, which left these joints in a few days, and lodged in the right knee. No other joints became involved; but he grew steadily worse under treatment for rheumatism, and emaciated rapidly after the involvement of the knee. When first seen by Dr. Ketch, he presented the facies of extreme suffering; the knee-joint was flexed beyond 90°; and was very much swollen, and excessively tender; there was manifest atrophy of the thigh and calf; pulse 120, temperature 103.5° F. He had had no chill. Anodynes were constantly required, and his general health was failing rapidly. The urine was abundant, and was free from albumen. Urates were in excess. The acute symptoms continued unabated after the constant application of ice, and the administration of morphine and the salicylate of soda for several days, the patient was etherized on July 12th, and the knee straightened with the exercise of as little force as possible. Adhesive plasters were applied from below the knee to above the malleoli, and plaster-of-Paris over this, with reinforcements by steel bars, the joint being left exposed. The limb was elevated, ice-bags applied to the knee, and traction made in a straight line by a weight of ten pounds. This was

followed by speedy relief, and a reduction of the temperature to 100° F. On the following day, the swelling had greatly increased, but the limb could be handled quite freely. The joint was firmly bandaged, and the ice continued. On July 16th, Dr. Gibney saw the patient, and advised a continuance of the treatment regardless of the swelling. The patient did not then require anodynes; appetite was improving; and the temperature had fallen to 99° F. Ice-bags were continued during the month of August, and the local tenderness diminished more rapidly than the pain on motion. When the splint was removed early in October, there was scarcely any motion at the articulation, and the joint could be freely handled without complaint. A retention splint was applied, and the patient allowed to go about on crutches.

In April, 1889, the ankylosis was complete, and he was enabled to return to work. He could, at present, walk long distances without fatigue, and his general condition was good. The chief points of interest in the case, were regarding the etiology and the treatment. He believed that there were cases of rheumatism like this one, in which the rheumatic process was modified or entirely changed in character. The presence of a poison in the system was undoubted; but it was remarkable that it should have been so mild at the time the elbow and thumb were attacked; and then have become so concentrated in the knee-joint as to practically destroy it. Rheumatoid arthritis was usually a chronic process involving numerous joints, and eventually crippling them; but such a process was not found in the present instance. The subject of treatment was important as bearing on the treatment of joints affected with rheumatism; and he was positive that his case would have resulted in a bad deformity, if he had not, in the beginning of his treatment, secured a good position of the limb.

DR. GIBNEY had seen a great many cases of hematoma of the sterno-cleido mastoid muscle, and they invariably got well. He had often wondered whether in some cases of congenital torticollis, actual shortening of the muscle had not been caused by long-continued holding of the head in one position, necessitated by the presence originally of a large hematoma. In these cases of hematoma, there was probably laceration of some of the muscular fibres, with escape of the blood into the sheath, or into the muscular tissue itself.

DR. N. M. SHAFFER said that he had made measurements of the length of the sterno-mastoid muscle in these cases, as well as in normal cases, and his observations showed that there was an arrest of development in the affected muscle, which suggested a possible central lesion, involving the spinal accessory nerve. These cases might arise from traumatism; but unless the destruction of muscular tissue was very great, it would not account for the total arrest of growth.

DR. KETCH thought that the existence of some deformity in Dr. Phelps's case after such extensive division of the muscles, showed the fallacy of depending altogether upon dividing muscles for the rectification of the deformity of hip disease. As long as the bone disease was active, and muscular spasm was present, deformity would return from this spasm, even after division of the muscles.

DR. SHAFFER also thought that division of the muscles offered only a temporary relief. He had frequently seen recurrence of the deformity after such a procedure in disease of various joints, and especially

in cases of tetanoid paraplegia. An examination under ether would determine the amount of muscular resistance; and the breaking up of the intracapsular and extracapsular adhesions, together with subsequent maintenance of the straight position, were all that could be expected in the way of preventing ultimate deformity.

DR. R. H. SAYRE said that much less traumatism was inflicted by dividing the muscles first, rather than by trying to reduce the deformity with the muscles in a state of tension. Dr. Ketch's remarks simply emphasized the importance of proper mechanical treatment after division of the muscles.

DR. KETCH said that if the reduction of the deformity could be accomplished effectually by mechanical treatment alone, he did not see the advantage of the operation. In answer to a question from Dr. Phelps as to what he would do with a deformity which had not yielded after one year's treatment by traction, he said that such a deformity was probably due to intra-articular changes, and was independent of the muscles; and he would therefore prefer exsection, or other bone operation.

DR. JOHN RIDLON wished to join the ranks of those who believed in rapid reduction of the deformity—slow reduction caused needless traumatism. In some cases the deformity could be rapidly reduced by mechanical means and without anaesthesia; others required anaesthesia; and still others were not reducible even then. In this latter class the first indication was a division of the soft parts, and the second, was to maintain the good position until a cure was effected. The average case of flexion through an arc of forty-five degrees, required from twelve to eighteen weeks of treatment with the traction splint, for its reduction; and the advocates of the traction splint had just confessed that the deformity would recur after such treatment. The deformity should be overcome in at least a fortnight. Thomas's hip-splint would keep the leg straight, and prevent flexion, adduction and abduction.

DR. A. B. JUDSON had not found that the muscles seriously interfered, in the acute stage of the disease, with the reduction of the deformity; and he considered that the reduction could be effected by slow and painless methods, without any harm to the patient. The difficulty in overcoming the deformity was a purely mechanical one, arising from insufficient leverage,—only the short distance from the acetabulum to the crest of the ilium.

DR. PHELPS, in closing the discussion on his case, said that the muscles were not divided to overcome reflex muscular spasm, but to overcome deformity; and in obstinate cases of long standing, like the one just presented, this was a safe procedure; while excision of the hip-joint was a serious one. He had not wished to cut the muscles more deeply, and the deformity, although not completely reduced at the time of operation in October, was being constantly diminished by the treatment employed. Statistics showed that a very small percentage of cases treated solely by mechanical means recovered without deformity; and therefore a resort to operative methods in a certain class of cases, and subsequent mechanical treatment, offered better hopes of success. He would be sorry to cut a tendon and have the case relapse; it would indicate improper treatment. He did not believe in trying to overcome the deformity by Thomas's splint,

or any other. During the treatment, in order to get proper leverage, and hold the patient quiet, a long splint was applied to the well leg, extending to the axilla, and the body, limb and splint enveloped in plaster-of-Paris. No splint could overcome the deformity, or possibly prevent it, which did not pass up to the thorax. The idea of allowing the patient to walk upon a splint, or upon the diseased limb, was a heresy, which we would eventually renounce. The patient, in his opinion, should use crutches, and he thought that Thomas struck in the right direction; but the splint should be fitted to the patient, and not the patient to the splint. Extension in a line with the axis of the neck of the femur was also necessary to relieve intra-articular pressure by overcoming the contraction of the adductor and abductor muscles.

DR. JUDSON thought the physiognomy of the case of partial ankylosis of the jaw was one of arthritis, and the deformity was directly due to the inability to use the jaw, and was not the result of the peculiar shape of the bone. Operation seemed much more successful than the stretching process.

DR. PHELPS concurred in this opinion, and added that in his experience, good results had followed resection of *one* of the temporo-maxillary articulations, as ankylosis was usually found only in one articulation. An incision, one and a quarter inches long, was made along the zygoma, and the articulation exposed. Chiseling away the articular surface was all that was necessary to cure the case. His cases had presented evidences of arthritis. The ankylosed joint was always on the side of non-development.

DR. SHAFFER remarked that if he had not heard the history of the case he would have supposed that the patient had had Pott's disease, and had been treated with an apparatus in which the chin-piece had been forced too far backward. He thought there was much rigidity on both sides of the jaw. If the part relaxed under ether, the evidence would be in favor of arthritis; but if not, it would indicate a permanent contracture, and would demand operation.

DR. GIBNEY said with reference to the case of posterior deformity of the tibia, that nothing but an osteotomy would correct the deformity. While under ether, the operator should endeavor to bring the fragments nearly into line, and then apply retentive apparatus. Subsequently, a supra-condyloid osteotomy would be needed. By doing a Macewen's or a Macormac's operation, the subsequent dressings would in a great measure correct the antero-lateral curvature. He had frequently seen this occur, sometimes to a marked extent. It was possible that the long rest in bed might have made the bone more yielding.

DR. SHAFFER thought that the case of arthritis presented by Dr. Ketch, answered very well the complete description given by Niemeyer, of arthritis deformans. He considered this nothing more than chronic articular rheumatism, and he had seen it both with and without high fever. It closely resembled gonorrhreal rheumatism, even in cases where gonorrhea could be absolutely eliminated.

DR. H. W. BERG said that he had seen a case of gonorrhreal rheumatism of the ankle-joint, which was quite thoroughly ankylosed, and did not recover its function for nearly two years. In such cases the lesion affected chiefly the soft parts, the inflammatory products binding down the tissues so firmly that the joint was virtually ankylosed.

DR. R. H. SAYRE had seen a severe case of arthritis similar to the one presented. After confinement to bed for eight months, suffering from severe pain and high fever, the knee-joint seemed to be absolutely ankylosed, and the patella immovable; but vigorous and persistent massage had secured, after about one year, pretty fair movement. The fact that the joint, in the case presented, was a little tender, was in favor of the ankylosis not being complete; for the tenderness arose from the pain caused by an almost imperceptible motion of the joint. Persistent and careful efforts at moving the knee-joint, not sufficient to cause pain, lasting many hours, would probably give the patient a movable joint.

DR. JUDSON called attention to the admirable position of the limb, remarking that a perfectly straight limb was much more stable than one bent at ever so slight an angle. These cases of stiff knee should wear a "lift" on the shoe of the well side, to enable the stiff knee to readily swing past the other, and so avoid awkward tilting of the pelvis at each step.

DR. PHELPS thought that in Dr. Ketch's case there was fibrous ankylosis, and that by breaking this up, motion could be secured. In one such case, while forcibly reducing the deformity, the femur was fractured without the exercise of much force; and he called attention to this, because, after prolonged rest in one position, the bone frequently underwent fatty degeneration, sometimes only a shell of bone remaining. Union of the fracture in his case, took place normally. He did not think there was much danger of exciting inflammation by forcible manipulation in these cases, unless the joint had previously been purulent.

DR. SHAFFER's experience had led him to believe that there was considerable danger of exciting inflammation by such treatment; and he would prefer a stiff joint in good position to incurring such risks.

DR. KETCH, in closing the discussion, said that he believed his case belonged to a class which had never been accurately described. In ordinary cases of arthritis deformans, there was involvement of other joints. This was not true of his case; and the sudden onset of such acute symptoms, and the speedy occurrence of ankylosis, were certainly unique. His patient had far too useful a limb to make him desire to incur any risks by employing forcible manipulation.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

T. F. SHERMAN, M.D., SECRETARY.

REGULAR Meeting, Monday evening, February 3d,
DR. J. H. McCOLLOM in the chair.

DR. M. H. RICHARDSON read a paper on

SUPPURATIVE INFLAMMATION OF THE KNEE-JOINT TREATED BY DRAINAGE THROUGH THE POPLITEAL SPACE.¹

DR. CABOT asked the reader how far into the joint he would carry the end of the tube, it being in the popliteal space?

DR. RICHARDSON said: It is impossible to carry it in between the condyles. If you carry a drainage-tube in between the condyles, and shut the knee up

you will crush it. I tried it on the cadaver with a steel director, and crooked it all up. There is plenty of room for drainage, however, on account of the shape of the femur. It would be better to put one tube above and one below, than one on each side.

DR. CABOT: It seems to me a tube through the popliteal space, unless supplemented by a tube above, would be rather precarious. Inasmuch as the end of the tube would project only a very short distance into the joint, I should think it might be easily displaced. Carrying the tubes carefully behind in the manner Dr. Richardson has shown would be, I should think, very satisfactory.

In connection with this subject I should like to speak of a case which is interesting as showing how good the drainage of the joint can be made by lateral drainage. The patient had an enormous old synovitis. Compression had made no diminution in its size, and almost everything had been tried. I etherized him, and introduced first an aspirating needle, and nothing came; then a large trocar, and nothing came, and finally, I made a large incision, and emptied out of the joint a double handful of large clots of fibrin, I suppose they would be called, very tough and very large. Then the joint became flaccid and came down, and I introduced the tubes that Dr. Richardson has spoken of, only I introduced two below, one on each side, and also entering the joint from above. Through this upper opening all the fibrinous material had been removed, and afterwards the opening was used for drainage. The temperature hardly went above the normal line. The man made a first-rate recovery with good motion in the joint, showing that the drainage was perfectly free. I have used this method of drainage in a great many cases. If I had drained through the popliteal space I should have feared that the tube might more easily slip out of the joint cavity than a tube that would reach in some distance from the side.

DR. RICHARDSON: In anteroposterior drainage there is plenty of room for the tube to go right beside the crucial ligaments. I think Dr. Cabot is somewhat mistaken in regard to popliteal drainage. There are large spaces on each side of the check ligaments allowing room enough for drainage.

DR. C. B. PORTER: Dr. Richardson's statement I am ready to accept, that there is plenty of room at the side of the crucial ligaments, because he has tried it to see; but my impression in regard to the conformation of the joint was that there was a very small amount of space. I have had no experience with regard to posterior drainage through the popliteal space. I have had considerable experience with regard to lateral drainage, and I cannot at this moment recall a case in which it was otherwise than satisfactory. I think, however, that the secret of success by lateral drainage is the thorough manner in which the joint is cleansed at the time of operation, and the manner in which it is kept aseptic after the operation. I have had to resort in a number of cases to putting the leg into an antiseptic bath, and keeping it there by the hour, allowing the antiseptic fluid, in that way, to penetrate all parts of the joint. I have in mind now a child who had acute suppurative synovitis from opening the joint with a nasty piece of tin. The wound was sewed up, and a number of days later the boy was brought to the Massachusetts Hospital. The boy was treated by a phenyle bath every day for two or three days, until the temper-

¹ Publication deferred.

ature became normal. He recovered with perfect motion; but the secret of recovery to my mind was not so much in the perfect drainage of the joint, as rendering the joint perfectly aseptic by the use of phenol.

Within the last week I have had occasion to unite the patella, and the ligamentum patellae in a child who was blown off the train in crossing from one platform to another; and during the last three days he has had a normal temperature. The only drainage-tube was a quill drainage-tube after syringing the joint. He had quite a variable temperature for a short time, but I attributed it to his general condition. He received at the same time a severe scalp wound down to the skull and a lacerated wound on the other leg, which looked as though some one had started to do excision of the knee on both joints, one opening the patella and ligament, and the other laying them bare.

Dr. Cabot's criticism with regard to the ease with which a tube would escape from the posterior surface of the joint, is one which needs further elucidation before surgeons would accept it. The popliteal space is, in many thighs, a very deep space to go into, and it seems to me that the only space is the one Dr. Richardson has represented inside of the popliteal artery. The nerve is to the outside, the artery to the inside, and the vein between, but all on different planes. The nerve is most superficial, and finally before you reach the artery in that line, you have arrived at the midline of the popliteal space. The knee-joint is pretty deep in a good many popliteal spaces, and it makes a deep dissection in a small triangular space; and that in the hands of any other than a skilled surgeon or anatomist, is a much more dangerous operation to the patient than a more free incision on the sides. I think the great point is rendering the joint thoroughly antiseptic on opening it. I think we shall achieve more brilliant results in that way, than by trying to establish any better drainage than we have.

DR. A. T. CABOT showed a specimen of

DERMOID CYST OF THE OVARY,

containing a large mass of hair. The fluid which was drawn from this cyst was thick and oily, but ran easily through a small trocar; on standing it hardened into a mass which had exactly the appearance of ordinary butter.

The patient was a young woman, married, and had had one miscarriage. The tumor had been discovered seven or eight years ago, being at that time smaller than a hen's egg. Its growth had been slow, and today, when removed by operation, it was but little larger than an adult fist. For the past year or more it had caused much pelvic pain, especially marked when it was crowded down into the pelvis alongside of the uterus; at such times, Dr. C. M. Garland, who was in attendance, was able to afford relief by lifting the tumor to a point where it was not wedged.

It was quite adherent, apparently owing to the slight inflammation which started up from time to time around it.

DR. FAIRFAX IRWIN, Surgeon Marine Hospital Service, showed

A LARGE SURGICAL KIDNEY,

and gave the following history of the case.

L. C., aged thirty-eight years, seaman, was admitted to the United States Marine Hospital, Chelsea, Mass.,

November 18, 1889, and died February 3, 1890. The patient was admitted for organic stricture of the urethra with perineal and rectal urinary fistulae. The stricture was very deep, near the neck of the bladder, and by reason of its cicatricial character, and the numerous fistulae, very difficult to enter. A Banks' filiform bougie, however, was passed every other day, with a view of dilating for Otis' urethrotome. Treatment proceeded with many interruptions until the urethra was thought to be sufficiently dilated. Nothing abnormal was found in the urine, and a day for the operation was set. Influenza, however, appeared January 15, evening temperature 39.4° C. The temperature showed a downward tendency until January 27 it became subnormal. At this time catarrhal pneumonia supervened, temperature sank lower and for the last three days of life ranged between 35° C. and 36° C. The patient died February 3, 1890.

Small doses of quinia were given early in the disease, but no other antipyretics, as might be supposed from the temperature. Alcohol, tincture of digitalis and ammonia were used.

There was some constipation but no trouble with urine. Surgical kidney was thought probable from the long-continued obstruction of the urethra.

Autopsy five hours after death.—Body well nourished. Slight rigor mortis. Heart and pericardium normal; weight of heart, 380 gms.

Lungs: Marked inflammation of finer and terminal bronchial tubes; lung-tissue highly congested, with some pleural ecchymosis. Pleural adhesions general and of recent formation. Weight of right lung, 600 gms.; left lung, 417 gms.

Liver normal; weight, 1,790 gms.; but was displaced upwards considerably by the enlarged kidney beneath it.

Right kidney enormously enlarged, with four or five large cysts filled with purulent urine. The walls of the cysts were very thick, about two centimetres, except over the largest cyst, over which there was nothing but the capsule of the kidney. The cortical and medullary substance was filled with small abscesses, containing pus. All the cysts together contained about five hundred cubic centimetres of fluid. The ureter was completely occluded by the new growth, which encircled the gland. Weight, 1,335 gms.

The left kidney weighed 760 gms., and was intimately adherent to the abdominal walls, and the descending colon. Kidney tissue, with the exception of a narrow ring of cortical substance, retaining to a slight degree the outlines of the gland, was replaced by the new growth which extended down into the pelvis, along with the ureter, involving all the vessels and nerves in that region, and completely investing the bladder except above and in front. The mucous membrane of the bladder was paler than usual, but no other abnormality was seen.

The descending colon was filled with hardened feces, due to the obstruction.

This new growth had all the macroscopical appearances of adipose tissue, but was harder on section.

On the posterior part of the membranous urethra was an organic stricture, almost entirely occluding its lumen, and just behind it were several fistulae, one leading into the rectum, one into an abscess just in front of the prostate gland, and a third opening on the perineum.

DR. M. H. RICHARDSON showed a patient who had

had successively the supraorbital, infraorbital at Meckel's ganglion, the buccal, inferior dental, and the inferior maxillary nerve destroyed. A striking feature was the slight deformity caused by these operations. The operation ought not to be called a new one, for I think it may be practically the same as Pancoast's operation. It seems to me it is an operation any anatomist would have done in this way and in no other way.

Recent Literature.

Enquête sur la Grippe.

We have received from the French Academy of Medicine a copy of their circular with the above title. The scope of the inquiry includes a series of questions which are quite similar to those embraced in the circular of the State Board of Health of Massachusetts issued last winter. They are as follows:

(1) Date du début de l'épidémie: (a) dans les grandes villes, (b) dans les petites villes, (c) dans les campagnes.

(2) Date du début de l'augmentation de la mortalité (complications): (a) dans les grandes villes, (b) dans les petites villes, (c) dans les campagnes.

(3) Semaine dans laquelle la mortalité a été à son maximum: (a) dans les grandes villes, (b) dans les petites villes, (c) dans les campagnes.

(4) Date à laquelle l'épidémie a pu être considérée comme terminée: (a) dans les grandes villes, (b) dans les petites villes, (c) dans les campagnes.

(5) Faits démontrant la transmission: (a) prisons, (b) collectivités, (c) bateaux. Tenir compte dans cette étude des voies de communications (chemin de fer routes, etc.?).

(6) Formes de la maladie.

Quelle a été la forme au début?

A quel moment sont apparues les complications pulmonaires?

Part des ces complications dans la mortalité.

Rôle de ces complications dans la transmission.

Rechutes.

Gripes prolongées.

(7) Influence des états morbides antérieurs sur la lithalite. (Maladies du cœur, phthisie; affections cérébrales, médullaires.)

(8) Recherches microbiologiques.

(9) Observations particulières.

— The final report of the Johnstown Flood Relief Commission gives an account of the disposition of the \$3,740,000 that was poured through their hands. One paragraph of this document refers to the early, constant and yet unended medical relief that had its origin in the great calamity. It is not generally known, says the New York *Medical Journal*, that the sum of \$40,000 has been set apart for the construction and equipment of a memorial hospital, and that a committee of the commission is now engaged upon the work. This hospital, when completed, will replace that which was established by the Red Cross Society of Philadelphia, and afterwards transferred to the charge of the local profession. The commission was led to construct the hospital by the evident necessity, during the present generation at least, of furnishing medical aid to many injured survivors of the great flood.

THE BOSTON Medical and Surgical Journal.

THURSDAY, SEPTEMBER 18, 1890.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 28 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMERELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

POST-GRADUATE STUDY IN ENGLAND.

It is often a source of surprise to many that American students of medicine should prefer to supplement their studies by additional work in France or Germany rather than in England, and the concourse of students to Vienna, is looked upon as a matter of fashion.

London possesses many hospitals well filled, and men of the greatest eminence as teachers whose names are well-known on this side of the Atlantic, and who ought to attract many of the students who now flock to the German universities. As a matter of fact, few students from the United States pretend to do any studying in London. A few visits to the hospitals to compare them with those of their native country, and note the most obvious differences, and to catch a glimpse of the men whose names have the greatest attraction, comprise the general experience of the American. Those who go further in the medical schools of London are few indeed. The reasons are obviously not in the want of clinical material nor of eminent teachers, but in the lack of opportunities for special study for qualified practitioners.

One of the great attractions of study at Vienna lies in the fact that the young medical graduate can, without trouble, enroll himself as a member of classes for the study of any particular branch of medicine. Such classes are numerous. In London one does not easily gain the right to watch the clinical procedures without becoming a regularly enrolled member of the school, and regular courses for post-graduates available for graduates of the medical schools of other countries were practically unknown until the present year. Post-graduate instruction has this year been undertaken, and the prospectus of its third course is before us. The general plan differs from the post-graduate instruction of this country very decidedly in that it consists of a definite course of seventy-two lectures and demonstrations extending over a period of two months, from October 13th to December 5th, and embracing the practice at the following hospitals: the Brompton Hospital for Diseases of the Chest, the

Great Ormond Street Children's Hospital, the Hospital for the Paralyzed and Epileptic, the Moorfields Ophthalmic Hospital, the Hospital for Diseases of the Skin, and the New Infirmary at Paddington. The lecturers number twenty-nine, and comprise some of the best known of English medical men. The course, itself, is an attractive one to those desiring general culture, but not to one anxious to perfect himself in special subjects. But the practice of the hospitals mentioned is opened to gentlemen attending the course on payment of small fees. This latter point is a great concession, and adds very materially to the attractiveness of the prospectus.

The number of graduates of American medical schools who desire to supplement their American studies by further study abroad is very great, and if opportunity is offered in England, the ease of access and the advantage of their native language cannot fail to attract many.

ON THE TREATMENT OF ANÆMIA.

At the Berlin Congress, Laache, of Christiania, Norway, referee, spoke of the treatment of anæmia. We must confess, he said, that in the domain of therapeutics, we are still almost entirely reduced to empiricism.

In the first place, we are to attend to diet and other hygienic measures. The diet should vary according to the state of the digestion, and should especially be free from sameness. The benefits of forced feeding and of artificial aliments (peptones and the like) are very doubtful.

There is only one certain indication for iron, namely, true primary chlorosis. Here it acts as a real specific, just like quinine on malarial fever. But as to the *modus operandi* of iron, we are in the dark. The most recent hypotheses according to which it acts as a simple haemostatic in the intestine, are far from being proved. The speaker preferred Blaud's pills to any other ferruginous preparation. If they are not borne, he tries the solution of albuminate of iron.

Arsenic gives especially good results in progressive pernicious anæmia. Its mode of action is as obscure as is that of iron. We know, however, that in the cases where iron is useful (chlorosis) the hemoglobin is diminished absolutely (globules are few in number and pale), while in pernicious anæmia, the hemoglobin is only relatively diminished; the globules are not pale, but of a deeper hue than in the normal state.

Iron, then, seems to act particularly on the hemoglobin.

In certain cases, purgatives are good in chlorosis; some have even designated a special form as *fecal anæmia*. Here, we may suppose the existence of a chronic poisoning by feces stagnating in the intestine.

There is a difference of opinion as to the utility of oxygen-inhalations.

Transfusion is especially indicated in pernicious or post-hæmorrhagic anæmia.

Koenig, of St. Petersburg, at the same meeting alluded to the benefits which he had derived from subcutaneous injections of Fowler's solution in pernicious anæmia. He injects five drops of this solution diluted with twice as much water, and continues the injections once a day for eight or ten weeks.

MEDICAL NOTES.

— "A jelly-fish slavery" is the term applied by Dr. Norman Kerr in the recent discussion on hypnotism at the meeting of the British Medical Association to the condition of hypnotized persons, a condition, he adds, worse than days and nights of pain.

— The exact statement as to the composition of the Berlin Congress by nations is given officially as follows: On Tuesday evening at 6 o'clock there were 7,056 members' cards sold. Of these, 5,561 were visiting physicians; 116 were contributors of papers, etc., in the meeting; 1,379 were ladies' cards. Of the 5,561 visiting medical male members there were from the provinces of Germany, outside Berlin, 1,658; from the town of Berlin alone, 1,157; Austria-Hungary, 257; Great Britain and Ireland, 353; Netherlands, 111; Belgium, 61; Luxembourg, 2; France, 171; Switzerland, 64; Italy, 144; Spain, 40; Portugal, 5; Sweden, 106; Norway, 58; Denmark, 139; Russia, 421; Turkey, 12; Roumania, 32; Bulgaria, 5; Greece, 5; Malta, 2; Monaco, 1; Servia, 2; United States of America, 623; Canada, 24; Brazil, 12; Chili, 11; Cuba, 4; Trinidad, 1; Mexico, 6; Hayti, 1; different parts of America, 24; Egypt, 8; Cape Colony, 1; other parts of Africa, 5; China, 2; Japan, 22; East Indies, 2; India, 2; Australia, 7. A few hundreds who came during the last four days of the Congress are not included in this analysis.

— Dr. Howard Smith, a special quarantine inspector, detailed in Central America to report to the New Orleans Board of Health cases of yellow or suspicious fevers there, has just sent to the board the following report:

"The whole of this coast is malarial, but I have not been able to discover any yellow fever. One reason that some of the fevers are so malignant is on account of the habits of the people; they drink to excess a liquor called white rum, said to be almost a poison, and after getting drunk, lie down on the wet sand or exposed to the night air. Of course fever follows, and they will suffer from several attacks the first year or two. Their food consists of fruits, salt and fresh meats, but not cooked in the best style. The climate is delightful, and with care there is no reason why the people should not be healthy. Ruatan and Truxillo are very clean towns. There is no danger to the United States of fever on the Spanish Honduras coast. There is, no doubt, some yellow fever there, but the principal sickness is malaria."

— Among the outbreaks of cholera which occurred in Burma last year, says the *Indian Medical Gazette*,

there was a remarkably sudden visitation at the Moulmein Jail. One evening the prisoners were conducted to their dormitories in the usual manner without the slightest indication that there was anything wrong. At midnight the seizures commenced, and by six o'clock the following morning nine men had been attacked, and every one of them died. When the day came to a close 31 out of a total of 674 convicts were struck down, and the following day the number of seizures was increased by 17, giving for the two days 48 attacks, of which 38 ended fatally. On the third day there were 15 more seizures, so that in three days ten per cent. of the jail population suffered. Cholera camps were formed outside "the zone of jail influences," but it was some time before the scourge could be shaken off, and by order of the commissioner 136 convicts were released.

— A correspondent writing to a daily contemporary regarding the cholera in Spain and Egypt, says that orders by the Egyptian Government for the temporary closing of the great carpet and rug bazaars at Cairo and Alexandria, where so many thousands of good American dollars change hands, are momentarily expected. Similar measures were adopted during the epidemic of 1883, for the carpet bazaars are most active agents in the spread of the malady, not so much by reason of the vast crowds which assemble there, but owing to the fact that nearly all the finest rugs and prayer-carpets on sale have previously been used to wrap up the corpses of wealthy Persians, Turks and Indians, whose remains had been conveyed to the sacred cities of Medina and Mecca for burial. The rugs, after the final interment of the bodies, become the perquisites of the attendants trusted with the conveyance of the corpse to the holy cities, and they lose no time in selling them at the best possible prices to dealers, through whose hands they finally reach the bazaar. It is well, therefore, to bear in mind the fact that the more valuable and the more beautiful the Eastern rug or prayer-carpet may be, the more certain it is to have constituted the shroud of some Turkish or Persian corpse during its trip across the scorching Arabian deserts to Mecca.

NEW ENGLAND.

— The death-rate of Boston is now computed on a population of 446,000, instead of 418,000, as heretofore, the figures of the present census being substituted for an estimate.

— The Rhode Island Medical Society held its quarterly meeting in Providence, September 11th. President John W. Mitchell, M.D., was in the chair; Dr. J. Frederick Holler read the paper of the day on physical deterioration in the people of our age and some remedial suggestions.

NEW YORK.

— On September 9th Coroner Levy held an inquest in the case of the typhoid fever patient at Bellevue Hospital, who recently died of an overdose of carbolic

acid administered by Lemuel N. Jaynes, an under nurse. The drift of the inquiry hinged on the entry made in the ward book by the physician in charge, and the discrepancies between it and labels on a bottle from which the nurse should have taken a dose of glycerine and carbolic acid, and on a bottle of undiluted carbolic acid. From the latter Jaynes gave a fatal dose, as previously reported. The jury found that Jaynes was negligent, but also that the fatal result was partly attributable to the authorities of Bellevue Hospital, who had neglected to properly label the mixture prescribed, and allowed medicines to be mixed with violent poisons. Moreover, that medicines and poisons were in the custody of inexperienced nurse pupils; in this case, of one below the average intelligence, Jaynes having admitted, during his examination, that he gave *only* half a drachm of the pure carbolic acid, instead of a drachm, because he "thought it too strong a dose." In consequence of the verdict rendered, Jaynes was committed to the Tombs Prison, in default of \$2,500 bail, to await the action of the Grand Jury.

— Signor Jean Succi, the Italian fastner and African explorer, has arrived in New York, and intends giving here another public exhibition of fasting. His last exhibition was at the Royal Aquarium in London, where he fasted for forty days and two and a half hours. Here he will endeavor to beat his own record and all other records in fasting, as he will make the attempt to live without food for forty-five days. He alleges that after his fasts he has always had strength enough left to ride on horseback, to swim, or to fence.

— The American Dermatological Association met during the first week in September at Richfield Springs; holding two meetings a day, and visiting Otsego Lake, the observatory, and other points of interest. At their last session they invited Dr. Ranson, the consulting physician at the bath-house, to read a paper on the use of mineral waters in diseases of the skin, and passed some complimentary resolutions in regard to the Richfield springs and baths which concluded as follows: "The medical profession in America may congratulate itself upon now having at home, under the control of so competent a proprietor, baths which are not surpassed in adaptation to their purposes by any in Europe."

— Under the system heretofore in vogue, large numbers of the insane who are without means have been deprived of the benefits of the care and treatment to which they are entitled because of the private pay patients who have been received into the State asylums. The State Commission in Lunacy in carrying out the provisions of the law establishing State care for the indigent insane, has ordered that after the first of October no distinction shall be made between private and public patients, and that after this date no private patient is to be admitted to a State hospital except upon this condition.

Miscellany.

THE USE OF SKIN FROM PUPPIES IN SKIN-GRAFTING.

DR. M. E. VAN METER records, in the *Annals of Surgery* for August, 1890, what he believes to be an original use of puppy-grafts for the production of skin, as follows:

"A boy, fourteen years old, having in April last sustained severe and extensive burns, under treatment had accomplished the healing of them all, except certain granulating regions beneath the chin and lower jaw, and the right arm from elbow to fingers. Upon these surfaces skin-grafts were finally placed. For the neck, grafts were obtained from the arms of the father and brother of the patient; but for the arm, grafts were taken from two young puppies of the Mexican hairless breed, whose soft, white, hairless skin seemed to offer itself for the purpose with good prospect of successful results. The result was all that could be desired. The puppy-grafts proved to be superior to the human grafts; a greater proportion of them 'took,' and their subsequent rate of growth was much faster."

In this connection the editor refers to a similar case, in the *Lancet*, March 15, 1890, by Mr. Alexander Milro, of Edinburgh. The case is as follows:

"A boy, ten years old, presented an extensive ulcer on the left leg, resulting from a burn. The entire surface was covered with healthy granulations, but there was not the slightest attempt at cicatrization. It being impracticable to obtain sufficient human skin to cover the ulcers, a young black and white greyhound, seven days old, was killed with chloroform, and the whole of his anterior abdominal wall and flanks having been shaved, the flap of the skin thus marked out was dissected up, taking the entire thickness, leaving the subcutaneous fat. The skin was cut into strips, measuring six inches long by half an inch broad, which were firmly pressed into the previously cleaned ulcer in the long axis of the limb. Smaller grafts, about an inch square, were used to fill in spaces left between the larger ones. A considerable area over the inner side of the knee still remained bare: to cover it, the skin from the pup's tail was dissected up, unshaven. Over these grafts an antiseptic dressing was applied.

"On the first dressing, three days later, all the grafts but one small one had adhered. Some of the long strips sloughed later, but the smaller ones all did well. It was observed that the graft taken from the tail, which was not shaved, behaved exactly as the sponge does by promoting granulation. The hairs around the margins seemed to stimulate the granulations which grew on to the surface of the graft, and then spreading, completely swamped it. A few small grafts of human skin from a small boy were scattered here and there, two weeks later, to fill up gaps still left, and all did well. One or two spots still remaining a couple of days later, were covered with pieces of the skin of an old frog, but these failed to unite.

"Cicatrization was complete in six weeks after the first application of grafts. Seven months later there was absolutely no cicatrical contraction except where the tail skin was planted, and there it was very slight. The color of the skin was uniform, and very similar to that of the normal skin. There was no evidence of any development of hair or of cutaneous secretions.

The ordinary sensation was as good as in the other leg, and the temperature of both was the same."

The author believes the favorable outcome of the case to be mainly due to the age of the animal selected to furnish the grafts. In the first few days of extrauterine life the creature grows very rapidly, and, by grafting a large area of young tissue with a potentially great developmental power, the ulcerated area is quickly covered in, and the contraction prevented which invariably results after extensive burns when they are allowed to heal without artificial aid.

A TWO-HUNDRED-THOUSAND-DOLLAR LIBEL SUIT.

SUIT has been entered by William Radam, manufacturer of Radam's Microbe Killer, against the *Drugists Circular*, of New York, for \$200,000 damages, the largest amount, so far as heard from, that was ever asked for in a libel suit of this kind.

The pleadings show that the action is brought to recover damages claimed to have been done the business of the plaintiff by an article published in the *Drugists Circular* for September, 1889. This article gave the result of an analysis of the Microbe Killer made by Dr. R. G. Eccles, a prominent chemist of Brooklyn, who stated that an identical preparation could be made by the following formula:

Oil of vitriol (impure)	4 drachms.
Muriatic acid (impure)	"
Red wine, about	1 ounce.
Well or spring water	1 gallon.

This mixture, it was alleged, could be made at a cost of less than five cents per gallon, for which Radam charged three dollars.

It was further alleged that while, when properly used, sulphuric acid, the principal constituent of the Microbe Killer, was a valuable medicine, it was, when taken without due caution or advice, a slow but certain cumulative poison; and the theories advanced by Radam, as to the causes of diseases and the proper method of treatment, were alleged to be totally erroneous. Col. Robert G. Ingersoll, the famous lecturer, is the counsel for the plaintiff.

The *Drugists Circular*, which is published at 72 William Street, New York, expresses a desire to hear of any case in which unfavorable results have followed the administration of the Microbe Killer, or of any other fact that would be interesting under the circumstances. They claim to have published this analysis without malice, and with the sole intention of protecting the public from the loss of their health and money by the use of a dangerous nostrum.

CLINICAL STUDY OF RARITIES OR OF COMMON DISEASES.

THE approaching beginning of medical school sessions gives especial pertinence to the question of how far students shall follow the rare cases and startling operations of their clinics, and how far they shall study the more common-place diseases which will make the bulk of their future work, and on which their success or failure will after all depend. Our contemporary, the *Medical Press*, thinks too much time is spent on medical curiosities. A sound knowledge of principles, it says, will enable men to dispense

with any deep acquaintance with myxoedemas or acromyalies.

It adds: "Most of the experiments of pathology, and of what may be called the *caviles* of our calling, constitute but a handicap to the general practitioner. The same statement may be applied to much of the lumber of *materia medica* with which the newly-qualified man is loaded. Twenty or thirty drugs will carry him safely along, while the rest of the legion are dismissed from his memory, to be recalled, perhaps by the perusal of hospital reports, or by a consultant's prescription. It is of far more importance for him to know how to make his physic pleasant, than to be able to jot down half a dozen out-of-the-way and costly preparations. And so with the curiosities. He will be repaid by a study of homely diseases, such as rheumatism, syphilis, and the exanthems, in preference to the minutiae of late discoveries demanded of book-worms by high standard examinations. At the same time, it may be fully granted that the curiosities have a very high place in the advancement of scientific knowledge. Our contention is, that they are too much in evidence in the wards of our hospitals, in the class-rooms, and in the medical journals. No man of average acquirements, if he take an interest in his profession, would allow the rarer diseases altogether to escape his attention. During the curriculum there is quite enough straightforward grounding to be done in the outlines of ordinary disease and treatment. Another year of study has been declared a necessity, and it is a matter of moment to decide how that additional twelve months is to be spent. The opinion has been expressed emphatically enough in certain quarters, that it should be devoted to practical work. From this standpoint an infusion of well-educated general practitioners into the teaching ranks would not be without its advantages.

"In actual practice the surgeon cuts unconcernedly through whole mazes of minute named branches of nerves and arteries, while the physician looks carefully after his patient's surroundings, ignoring the hosts of remedies that are busily puffed on every hand. The student may well stand aghast as he glances through the pages of a modern reference book on *materia medica*. But he may take heart of grace, and rest assured that after he has learnt enough to satisfy his examiners, his acquaintance with most of the drugs will cease. The teachers and investigators of the subject, no doubt, do great and important service by their work. Now and then a discovery is made that takes the medical world by storm, and the virtues of some new substance are established. For each one that stands its trial, however, there are probably scores that sink into oblivion. Curiosities, however, are more closely connected with the road to fame; a fact which, to a great extent, accounts for their extreme prominence in the medical world."

THE RESPONSIBILITY OF THE PHYSICIAN FOR EXPERIMENTS UPON PATIENTS, EVEN WITH THE LATTER'S CONSENT.

A CASE was recently tried in a Cincinnati court, says the *Medical Record*, in which the conditions were rather peculiar, and in which the finding of the judge was of interest to others than the one directly concerned in the matter. It seems that a physician of that city was sued by a man who claimed to have been

injured by experiments with the Elixir of Youth. The man had been paralyzed for some time, and could get about only with much difficulty. The physician called him in as he was hobbling past his office, and proposed to try the effect of the "elixir" on his paralysis. The old man consented, and a charge of that stuff was injected into each leg. The result was that an abscess formed on his paralyzed leg, from which he suffered greatly.

The patient did not apply to the doctor for treatment, and the doctor made no charge for what he did. It was an experiment, attended with danger, which the doctor was eager to make, and the patient, with perhaps a limited understanding of the matter, seemed willing it should be tried.

It was contended by the defence that the case was not one of malpractice, nor could it quite be called an assault, and it fell short of the definition of a tort. Although the sufferings of the patient might be directly traceable to the doctor's act, yet it was a question whether the doctor did anything of which the law could take cognizance.

The jury, however, brought in a verdict against the defendant, assessing the damages at seventy-five dollars. The judge charged the jury that it is not malpractice where a physician treats a patient upon his own motion and without pay, but the physician is bound to use ordinary skill even under such circumstances, and if he does not use such skill, or in guilty of carelessness, he is guilty of a tort for which he is liable in damages.

Our contemporary expresses sympathy for the physician who was obliged to pay damages, yet holds that the decision was a just one. It will serve, at any rate, as a useful warning to others not to experiment carelessly with any medical fad that may be proposed, before they know anything about its merits or its dangers.

TWO MEDICO-LEGAL DECISIONS.

In the Brooklyn *Medical Journal*, September, 1890, is the report of a case of interest to doctors, taken from the last volume of "Decisions of the Court of Appeals of New York." The action was brought by a man named Alberti, against the Erie Railroad.

Alberti was a passenger, in July, 1885, on an express train of the Erie Road, and was seated in one of the sleeping-cars. His train came into collision with a partially-displaced door of a passing freight-car, which broke the windows and the partition between them, at which Alberti was sitting. He was struck by the broken pieces of glass and woodwork, and so injured that the muscles of his legs contracted, drawing them up against his body and rendering him helpless. Two points interesting to physicians occurred in the case.

It seems that Alberti lived in a village in Orange County in this State. He was treated by the physician of the little place, who also called in other practitioners of adjoining villages. The first doctor had never had such a case. The others had had a little experience in such cases, but were by no means specialists as to the trouble. It was some time before a specialist from New York city was sent for, at the suggestion of the village doctors, then at their wits' ends. The defence called a number of leading physicians, and proved that if such treatment as they would have pre-

sented had been given earlier, the injury would not have been so serious. The company then claimed that it was the duty of the injured man to have secured such proper attendance. The court divided on the question whether Alberti could prove that he was a poor man, in order that the jury might infer that he had not the means to send for a city doctor skilled in his trouble. Four judges voted that he was entitled to give such proof, on the ground that it was proper to show that he had not been negligent; that is, that he had done the best his means allowed, against the chief justice and another who voted the other way, Judge Brown, of Orange, well known here, not voting.

It was also objected by the lawyer for the railroad company, that the doctor who had first treated the injured man could not be allowed to disclose any information which he acquired in attending his patient. Upon this objection being made, the plaintiff's lawyer said that he waived the benefit of that rule of law. The objection was then overruled. The railroad company, on appeal, claimed that the lawyer of a party could not make such a waiver; that it was so personal a matter that no one could speak for him; that he could only act through his own speech or hand. The court held without dissent that the attorney of a client suing in his own behalf could make such a waiver in the course of a trial, the court intimating, however, that in the case of a suit by the representative of a deceased party, the power to make the waiver would have died with the deceased.

A CASE OF HYDATID TUMOR OF THE BRAIN —REMOVAL —RECOVERY.

DRS. JAMES GRAHAM, and C. P. B. Clubbe, of Sydney, Australia, report in the *Australasian Medical Gazette*, July 15, 1890, the first successful case of operation for cerebral hydatid in that colony. We condense the history.

C. G., aged sixteen years, a male, was a strong, healthy child, bright and active, and had been, up to present, free from any form of serious illness, except when at the age of ten years, he fell over a rock, a distance of twelve feet. He then lay unconscious for two days with his head drawn towards the right side. A few days afterwards he recovered, apparently without any bad effects from his fall, and has enjoyed good health up to the time of his present illness, which he dates from Christmas last.

His employer states that the boy was an intelligent and reliable servant, but that for several weeks before he was laid up he noticed that his memory was getting bad, and that he seemed dull and depressed.

The patient first complained of severe frontal headache after waking from a good night's rest, and on getting up felt giddy and sick. Everything seemed misty before him, and he noticed shortly afterwards, during the same day, that he was quite blind in his left eye.

An attack of headache and vomiting confined him bed for four days, and on getting up he said he felt much better only his sight was very dim, and he found he could not lift his legs as easily as he had been used to do. For about two weeks afterwards his sight seemed to improve, but the weakness in his legs increased. He noticed also that he could hardly use a knife with his right hand.

On admission the patient could give an intelligent history of his own health. He was well nourished and robust. His eyes were prominent, the pupils widely dilated, and reacted very feebly to light. He had a faint perception of light in the right eye, but the left was totally blind.

Hearing, taste and smell were normal. He walked like one steady a weight on his head, and leaned slightly towards the right side. He dragged the right leg slightly, and he had greater power of grasp with his left than with his right hand.

Superficial and deep reflexes were not altered, neither were sensation and muscular sense.

Ophthalmoscopic examination showed no paralysis of external ocular muscles. Both discs were in a condition of post-neuritic atrophy. The veins were large, the arteries considerably contracted, pointing to contraction of the exudation in the nerves. There had been more widespread exudation in the left eye than in the right. In the right eye it was confined to the disc and its immediate vicinity; in the left it was extended for some distance, obscuring the vessels in places.

For some weeks he seemed to improve under large doses of bromide and iodide of potash.

On the 17th of March the nurse reported that he had had a fit in the night, during which he moaned and struggled a good deal.

On the following morning he had complete loss of power in the right arm and in both legs; he had also an attack of headache and vomiting. The left eyelid slightly drooped, and the face was drawn a little to the left side. He lay in a drowsy condition for some days, and when questions were put to him, could only reply in monosyllables after some interval.

In the course of a week after this attack he regained power and movement, but in walking the dragging of the right leg was very marked, and the strength in the right arm was very feeble.

Perception of light was quite absent in both eyes, and the pupils no longer reacted to light. His mental condition had become much more obtuse, and mind and memory were practically a blank.

As it was evident that the pressure mainly involved the left motor area of the brain, and that the symptoms of a tumor in this region had become much more pronounced, Dr. Graham determined to submit the patient to operation without delay.

Mr. Clubbe conducted the surgical treatment of the case. After taking the usual precautions to render the scalp aseptic he trephined over the spot corresponding to the upper portion of the fissure of Rolando. In ascertaining the depth of bone which the instrument had reached, the quill suddenly passed through the dura mater, and its withdrawal was followed by pulsating jets of clear fluid. On removing the button of bone, which was thinned to about one-sixth of an inch, the exposed portion of the dura mater was found thickened, and on opening it a quantity of clear fluid escaped. A light reflected through the opening made, showed a collapsed hydatid cyst lying at the bottom of a large cavity. This was easily seized with a pair of forceps, and removed by gentle traction. The portion of the brain exposed showed that the pia mater was intact; from the presence of the cyst the brain substance corresponding to the motor area was bevelled into a cup-shaped cavity. It was evident that the hydatid had grown from the arachnoid membrane. The brain, while exposed to view, made no attempt to

expand. The cyst measured four inches in diameter, with a fluid capacity of nineteen ounces. The fluid gave the ordinary reaction of hydatid fluid. There was no scolices or daughter cysts. The interior of the hydatid wall was sacculated at different points. There was no evidence of an ecto-cyst in the seat of growth. The cavity was gently irrigated with a solution of perchloride of mercury, 1 in 10,000, and the dura mater stitched, except at one spot where a drainage-tube was inserted. A corresponding opening for the tube was made in the scalp, and the edges of the semi-lunar flap brought together. The dressing was serum gauze and antiseptic absorbent wool.

There was large discharge from the wound; the tube was removed the third day and though there were some alarming symptoms, after the fourteenth day he made steady improvement. He gradually but completely regained power in his right arm and leg. At the end of six weeks he was allowed to get out of bed and to begin walking in easy and short stages. In a day or two the habit of walking by himself became quite easy, and eight weeks from the operation he was quite smart and active on his legs.

There is also a marked improvement in his mental condition, his memory, which seemed to have become obliterated from the time of the operation, has now returned and he can recall facts and dates connected with his illness; as the patient puts it, "he feels all right, and is only waiting for his sight to come back."

The protrusion of the eyes, which was so well marked before the operation, has nearly all disappeared. The pupils are normal in size and readily react to light. He says, when asked if he can see, that daylight appears to him like a red light, but that at night everything is black. No positive evidence of returning vision has been manifested, and the structural changes in the fundi remain unaltered.

Correspondence.

THE BERLIN INTERNATIONAL MEDICAL CONGRESS.

SECTION OF OBSTETRICS AND GYNECOLOGY.

ANTISEPSIS IN MIDWIFERY. — VAGINAL EXTRIPATION OF THE UTERUS. — ARTIFICIAL PREMATURE DELIVERY. — ELECTROLYSIS OF MYOMATA.

BERLIN, August, 1890.

MR. EDITOR: — In describing the work of the Section for Obstetrics and Gynecology of the Tenth International Medical Congress, it will be best to confine myself to a general summing up and consideration of the papers read and of the practice suggested there, as it would require too much of your valuable space if I attempted even the briefest sketch of every one of the 118 papers which were read in the thirteen meetings of the Section, besides the four discussions of subjects which were held as appointed in the programme.

In general, it may be said that too many papers were read; because, in order to complete the list as determined upon beforehand for each session, it was necessary to confine the discussion of each paper within the narrowest limits. This was done both by a rule limiting the discussion of any paper to three participants, each of whom could speak not more than five minutes; and even more effectively by the feeling on the part of all present, that any considerable time spent in discussion would prevent some member from reading the paper which he had prepared. As a consequence, all of the 118 papers were read, or as

much of each as could be delivered in precisely ten minutes; and those members who could thoroughly understand all the three languages (German, English and French), and who virtuously attended all the sessions, had the satisfaction of anticipating the publication of the transactions by several months. On the other hand, the brief remarks of the fifty-one members who spoke in discussion might well have been expanded, and many more of the distinguished gentlemen present might well have spoken, to the great satisfaction and instruction of their fellow-members.

The names of the gentlemen who were inscribed at the meetings of the Section, as being present, reached the number of 450; but, of these, a large number being manifestly ignorant of any language but their own, were wandering about, to the disturbance of those who were conscientiously listening to the proceedings.

It is evident, that, if the participation in international meetings goes on increasing, it will be necessary to limit in some way the number of papers actually read, and to require some qualifications as to membership more than regular standing in the profession and the payment of a small fee.

With these preliminary remarks, which are in no way intended as a reflection on the very conscientious and energetic organizers and officers of the Section, who displayed the greatest affability, tact, discretion and endurance, I will proceed to consider the main features of the proceedings.

The four subjects previously selected for discussion were (1) Antiseptis in Midwifery, (2) Vaginal Extripation of the Uterus, (3) Artificial Premature Delivery, (4) Electrolysis of Myomata.

The first of these questions was evidently one of the greatest interest, not only to all practitioners of medicine, but to humanity as a whole, and to the authorities of all States and cities, who are entrusted with the support and management of the public charities.

The discussion was chiefly valuable as showing how widely the introduction of thorough ANTISEPSIS IN MIDWIFERY has spread, and how it has everywhere been followed by the same beneficial reduction of puerperal mortality and morbidity, and by a distinct improvement in the health of the women of all nations.

From Russia to America, and from Sweden to Italy, the representatives told the same story of the cessation of epidemics of puerperal fever which often used to carry the mortality to fifteen or eighteen per cent., of the puerperal women, so that now, one-half per cent. to one and one-half per cent., is all that is expected, and in hospitals, these represent not cases developed in the institutions, but those brought in already infected. A considerable part of the discussion related to the measures to be introduced and enforced among midwives.

As for the procedure to be employed in hospitals and in general practice, as far as may be required, it may be said that nothing new has been discovered since the general introduction of the use of solutions of bichloride of mercury, which can efficiently replace the latter. The whole principle, which is sufficiently familiar to your readers, being to make the vagina and external parts of the mother thoroughly clean and aseptic at the commencement of labor, preferably by the use of a sublimate solution, to have the hands and clothes of the accoucheur and nurse and all the surroundings of the patient perfectly clean and aseptic; and then the woman not being infected locally, will have no puerperal fever. Vaginal injections after delivery are, therefore, unnecessary, except in cases where, owing to the want of the above precautions or want of thoroughness in carrying them out, either a considerable fever has supervened or the lochia have become offensive.

This is substantially what I wrote to the JOURNAL in 1885, as the treatment then introduced into the hospitals in Berlin.

The only new fact emphasized at this Congress, was that in most cases it is entirely unnecessary to make any digital examination whatever, for the position of the child can be quite sufficiently determined by palpation of the abdomen, and if everything is normal there is no use in complicating

matters by digital examination. This is only a logical deduction from the principle once so pithily described by Credé. "He who has not examined a woman has not infected her."

Another fact of importance elicited by the discussion was that great lying-in hospitals, if properly managed, give an almost ideal safety, both for mother and child, and are in many respects preferable to small institutions where the patients are under the care of local midwives, such as were established, before aseptic times, in order to avert the danger of puerperal fever.

The only problem which now remains is to secure for women who are delivered at home any approximation to the security which they enjoy in well regulated institutions.

The principal participants in the discussion were Professors Slaviansky, of St. Petersburg; Priestly, of London; Stadfeldt, of Copenhagen; and Fritschl, of Breslau.

The second discussion on VAGINAL EXTRIPATION OF THE UTERUS, showed that since the last Congress in 1887, this operation has been widely adopted, and that the indications for its performance are now definitely understood, and accepted with substantial unanimity.

The principal speakers were Drs. Williams of London, Schauta of Prague, Péan and Pozzi of Paris, Olshausen, Landau and Martin of Berlin, Sajatsky of Moscow, Kaltenbach of Giessen, and Czerny of Heidelberg.

It seemed to be the opinion of all that

(1) Total vaginal extirpation of the uterus should always be performed as soon as cancer of any part of that organ is discovered, provided the disease has not advanced too far to permit of the removal of all diseased tissue and the state of the patient warrants the operation.

(2) That therefore, high amputation of the cervix for cancer should be abandoned.

(3) That vaginal extirpation of the uterus is a comparatively safe operation (for instance, Kaltenbach reported eighty cases with two deaths), Sajatsky stated that in Russia the operation has been found almost devoid of danger).

(4) That with all possible thoroughness of operation a very large number of relapses occur, fifty per cent. or more (Olshausen, Kaltenbach).

Differences as to the manner of operation were unessential. Most of the German surgeons use catgut ligatures, most of the French use clamps, each according to his taste and custom.

Olshausen, in his last twelve operations, after disinfecting the stumps of the broad ligaments and cutting the catgut ligatures short, returns the stumps into the abdominal cavity and closes the latter by uniting the opening in the vagina transversely with sutures.

Schauta recommended vaginal extirpation of the uterus for some cases of myoma, and of prolapse, and for recurrent glandular endometritis, which is apt to become malignant.

Martin would also operate in this manner for cases of inveterate metrorrhagia which cannot be cured otherwise.

The third subject for discussion was introduced by a scholarly paper by Professor Parvin of Philadelphia, in which was a careful *résumé* of the literature and statistics of the INDUCTION OF PREMATURE LABOR.

The indications which he set forth for such a procedure were uncontrollable vomiting; renal diseases; cardiac affections; pulmonary diseases, especially capillary bronchitis, edema, and advanced phthisis; diseases of the nervous system, particularly eclampsia and meningitis; acute infectious diseases; lastly, but most frequently, deformity of the pelvis. Out of 988 cases of induction of premature labor which the reader had collected, 870 were on account of deformity of the pelvis.

Quite an animated discussion followed, the chief point being the determination of the best method of inducing premature labor, and the limit of pelvic narrowness, at which this procedure should give place to Cesarean section in the interest of a viable child. It seemed to be agreed that the induction of labor, either by introduction into the uterus, of a pliable bougie (not a hollow catheter) and the use of hot douches, or by dilatation of the cervix by laminaria and

india-rubber bags is a reasonably safe procedure for the mother if performed aseptically. Calderine of Parma, reported, for instance, 305 cases with a maternal mortality of four and six-tenths per cent.; Fehling of Basel, sixty cases with no death of the mother, and eighty per cent. of living children; Leopold of Dresden, seventy-five cases with one death of the mother. On the other hand, out of forty-two cases of Cesarean section Leopold lost four, so that he was not inclined to recommend its introduction into general practice in cases where induction of premature labor could be performed with safety for the mother.

As for the chances of saving the child alive by this procedure, it seemed to be agreed that the smallest conjugate pelvic diameter through which a viable child can pass is seven and a half centimetres, while as a rule the conjugate diameter must be eight to nine and a half centimetres (three and one-fifth to three and two-fifths inches).

The question of the choice between Cesarean section and the induction of premature labor, where the pelvis is so narrow that the child must be sacrificed, was not fully discussed, but it seemed to be assumed that the former operation was limited to cases where the consent of the mother, the attendance of an experienced operator, and the advantages of a well-regulated hospital were added to the other indications, so that for general practice the induction of premature labor is to be considered as the operation of election.

The fourth and last subject appointed for discussion was ELECTROLYSIS IN GYNECOLOGY.

It is fair to observe that the presentation of the subject was somewhat one-sided, as all those gentlemen who were appointed to participate in it, namely: Drs. Apostoli, Keith, Cutler and Zweifel were known to be in favor of the use of electrolysis, while none of the German surgeons who strongly disapprove of this method of treatment, cared to express their views, as they did not wish to appear to be even scientifically inhospitable to their French guests, and as the modern use of electrolysis in gynecology is essentially a French specialty.

The subject was well-represented by Dr. Apostoli whose views on the treatment of myoma by electricity are, I presume, well-known to your readers. He also insisted on the value of this agent in other uterine affections, especially as a substitute for the curette in endometritis, and in amenorrhea, dysmenorrhea and menorrhagia; also in promoting the absorption of peri-uterine exudations. He warned, however, against the use of electricity in strong currents in cases of purulent salpingitis. In the last eight years Apostoli has made 11,499 applications of galvanic electricity on 912 patients, comprising 531 myomata, 133 cases of simple endometritis, and 248 cases of endometritis complicated with peri-uterine phlegmasia.

He reports three deaths resulting from operative faults in his applications; two cases of galvano-puncture of which one was for a sub-peritoneal fibroma, and one for an ovario-salpingitis. The third death was from galvano-puncture of an ovarian cyst mistaken for a fibroma. He has observed thirty cases of pregnancy among the women whom he has treated with galvanism.

Dr. Keith not being present, Dr. Ephraim Cutler gave a history of the early use of galvano-puncture in America for myomata, reported fifty cases, in eleven of which the tumor was said to have disappeared, while in four cases death ensued as a result of the treatment. Unfortunately, no one else present could report the complete disappearance of a myoma under electrolysis.

Professor Zweifel, of Leipzig, after a description of Apostoli's method, gave the results of his experience, stating that there could be no doubt that the treatment gave severe pain to the patients, although they learned to endure it. Electro-puncture he considered dangerous; the treatment was to be considered as symptomatic and not as radical, and under it there was no doubt that there is frequently a cessation of growth of the tumor, which is not always permanent, as sometimes the tumor begins to grow again later, while on the other hand, the tumor may become smaller, and this diminution may go on to a consid-

erable extent, not, however, to complete disappearance. The patients usually feel much better in regard to their pains and sufferings.

A large number of members related their experiences with electrolysis, mostly in a favorable sense; there was not wanting, however, a strong undercurrent of doubt, denial and ridicule, which although it found no open expression was freely indicated by various distinguished members in private conversation. If Philadelphia had been more fully represented at the Congress, the discussion of this subject would have been less one-sided.

As for the action of the constant electrical current there was nothing new advanced, so far as concerns the treatment of myomata, or fibroid tumors.

Dr. Goubaroff, of Moscow, claimed to have obtained good results in uterine cancer, from the use of galvanism, to control hemorrhage and pain; he astonished all present by recommending the use of a current of 1,000 milliamperes, under chloroform.

The speakers did not adequately discuss the question of the use of the galvanic current in chronic "parametritis," which was perhaps fortunate, inasmuch as a clear comprehension of the pathology of pelvic inflammations, did not seem to be very general, and while some found that exudates disappeared rapidly under the use of electrolysis and massage, no less an authority than Apostoli himself warned against the danger of the galvanic current in "suppurative phlegmasia of the appendages."

One thing was very evident, namely: that the use of galvanism in uterine and pelvic inflammations requires a diagnostic acumen and manipulative skill, and antiseptic thoroughness of a high degree, in order to avoid serious accidents. Just how much advantage is to be gained from its use under these conditions, is not settled as yet.

In another letter I will consider some of the papers which were read at this Section of the Congress.

Yours respectfully,
E. W. CUSHING, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 6, 1890.

Deaths reported 2,451; under five years of age 1,140; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 582; consumption 290, acute lung diseases 183, diarrhoeal diseases 346, typhoid fever 78, diphtheria and croup 76, whooping-cough 32, malarial fever 30, measles 8, scarlet fever 8, cerebro-spinal meningitis 4.

From whooping-cough, New York 11, Baltimore 6, Philadelphia 5, Brooklyn and Boston 3 each, Nashville, Cambridge, Lawrence and Salem 1 each. From malarial fever, New Orleans 13, Brooklyn 7, Baltimore 6, New York 4. From measles, New York 1, Brooklyn 1. From scarlet fever, Philadelphia 3, Brooklyn 2, New York 1, Boston 1, Washington 1. From cerebro-spinal meningitis, Lynn 2, New York 2, and Worcester 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,539, for the week ending August 23d, the death-rate was 21.0. Deaths reported 3,907: infants under one year 1,545, acute diseases of the respiratory organs

(London), 203, diarrhoea 705, measles 106, whooping-cough 72, scarlet fever 56, diphtheria 36, fever 24.

The death-rates ranged from 13.0 in Bristol to 31.7 in Preston, Birmingham 24.6, Bolton 24.8, Brighton 21.9, Hull 22.7, Leeds 20.4, Leicester 17.9, Liverpool 23.2, London 19.2, Manchester 26.8, Nottingham 15.5, Sheffield 27.6, Sunderland 23.4.

In Edinburgh 16.2, Glasgow 20.9, Dublin 20.5.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,539, for the week ending August 30th, the death-rate was 20.7. Deaths reported 3,857: infants under one year 1,386, acute diseases of the respiratory organs (London), 184, diarrhoea 599, measles 100, whooping-cough 84, scarlet fever 56, fever 43, diphtheria 39.

The death-rates ranged from 11.2 in Bristol to 35.2 in Newcastle-on-Tyne, Birmingham 21.7, Bradford 18.6, Hall 20.7, Leeds 18.3, Leicester 20.9, Liverpool 23.5, London 19.6, Manchester 27.6, Nottingham 12.6, Sheffield 28.2, Sunderland 22.5.

In Edinburgh 12.3, Glasgow 18.4, Dublin 23.8.

The meteorological record for the week ending Sept. 6, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom- eter.		Thermometer.			Relative Humidity.		Direction of Wind.		Velocity of Wind.		State of Weather.*		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 4, 1890, TO SEPTEMBER 12, 1890.

By direction of the Acting Secretary of War, First Lieutenant NATHAN S. JARVIS, assistant surgeon, is relieved from duty at Fort Verde, Arizona Territory, and will report in person to the commanding officer, San Carlos, Arizona Territory, for duty at that station. S. O. 208, Par. 2, A. G. O., Washington, D. C., September 5, 1890.

Leave of absence for one month, on surgeon's certificate of disability, is granted Major A. A. WOODRULL, surgeon, with permission to go beyond the limits of the department. S. O. 122, Par. 1, Department of the Missouri, September 5, 1890.

Leave of absence for one month, to take effect on or about October 20, 1890, is hereby granted First Lieutenant LEONARD WOOD, assistant surgeon, with permission to apply for an extension of one month. S. O. 74, Par. 1, Department of California, San Francisco, Cal., August 30, 1890.

Leave of absence for one month is granted Captain EDWARD C. CARTER, assistant surgeon United States army. S. O. 108, Par. 2, Headquarters Department of the Columbia, September 6, 1890.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 13, 1890.

THORON WOOLVERTON, medical director, ordered to U. S. S. "Philadelphia," September 15th.

THOMAS N. PENROSE, medical inspector, detached from the U. S. S. "Richmond."

J. E. GARDNER, passed assistant surgeon, detached from the U. S. C. S. C. "Albatross."

N. H. DRAKE, passed assistant surgeon, detached from the U. S. C. S. S. "McArthur," and to the U. S. F. C. S. "Albatross."

T. A. BERRYHILL, passed assistant surgeon, detached from the Hospital Mare Island, Cal., and to the U. S. C. S. S. "McArthur."

A. C. HEFFINGER, passed assistant surgeon, ordered before retiring board, October 1, 1890.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FROM AUGUST 12, 1890, TO SEPTEMBER 6, 1890.

VANSANT, JOHN, surgeon. Granted leave of absence for thirty days, to take effect upon return of Assistant Surgeon J. C. Perry to duty. September 5, 1890.

WYMAN, WALTER, surgeon. To proceed to Cape Charles Quarantine Station on special duty. August 25, 1890.

STONE, GEORGE W., surgeon. Granted leave of absence for four days. August 19, 1890.

CARMICHAEL, D. A., passed assistant surgeon. Leave of absence extended fifteen days. August 26, 1890.

AMES, R. P. M., passed assistant surgeon. To proceed to Memphis, Tenn., on temporary duty.

DEVAN, S. C., passed assistant surgeon. Leave extended five days on account of sickness. August 12, 1890.

WILLIAMS, L. L., passed assistant surgeon. Granted leave of absence for thirty days. September 5, 1890.

GOODWIN, H. F., assistant surgeon. Granted leave of absence for thirty days. August 23, 1890.

CORB, J. O., assistant surgeon. To proceed to Marine-Hospital, Detroit, Mich., for duty. August 16, 1890.

HUSSEY, H. H., assistant surgeon. Granted leave of absence for thirty days. August 19, 1890.

PERRY, J. C., assistant surgeon. Granted leave of absence for twenty days, to take effect when relieved. September 3, 1890.

YOUNG, G. B., assistant surgeon. To rejoin his station at St. Louis, Mo., when relieved. September 3, 1890.

APPOINTMENT.

ROSENTHAL, MILTON J., assistant surgeon. Commissioned as an assistant surgeon by the President, August 25, 1890. Ordered to Chicago, Ill., for temporary duty August 27, 1890.

DEATH.

In Taunton, Mass., September 15, 1890, Joseph Murphy, M.D., M.M.S.S., aged seventy-two years.

BOOKS AND PAMPHLETS RECEIVED.

Annual Report of the Board of Health for the City of Lowell, for the year 1889.

Address in Hygiene. By Thomas J. Mays, M. D., of Philadelphia. Reprint. 1890.

SEIZURES CHARACTERIZED BY SHOCK AND SUDDEN COMA.¹

BY ISRAEL T. DANA, A.M., M.D., PORTLAND,
Professor of Pathology and Practice in the Medical School of Maine.

SHOCK may be defined as a condition of sudden depression of the vital functions, especially the cardiac, respiratory and sensorial, by physical injury or strong mental emotion. **Coma** is a state of unconsciousness, of profound insensibility, from which it is impossible or difficult to arouse the patient. The elements, then, of the class of seizures defined in our title, are abruptness, violence, loss of consciousness, and depression of vital power. And these must be so developed and combined as to give character to the attack.

Syncope, with its characteristic feeblessness of heart-action and cerebral anemia, its constantly brief period of unconsciousness, its instantaneous and perfect recovery, its frequently trivial causation, and its trifling danger, is not usually reckoned a form of coma.

Coma, with more or less shock, is observed as an incident of many diseases, which it cannot be said to characterize. It may occur during the invasion, in the course of, or near the termination of a disease. In the last case it may be simply a manifestation of the final failure of vitality. It occurs in a great variety of diseased cerebral conditions, especially concussion and compression, anemia and hyperemia, extravasation of blood and serous effusion, inflammation, exhaustion, and sunstroke. It is found related to various convulsive affections, as epilepsy, hysteria, infantile reflex, puerperal and uremic convulsions. It is common in connection with fevers, both essential and symptomatic, continued and malarial, especially when hyperpyrexia is present. It is seen at the invasion of scarlatina and other eruptive fevers, often associated with convulsions in the case of children. Uremic coma is usually preceded by or accompanied with convulsions, and generally terminates fatally. Diabetic coma is sometimes met with, usually towards the end of the disease, and is often preceded by marked nervous phenomena. It usually progressively deepens to a fatal issue within two or three days. The breath is apt to take on a characteristic fruity odor, sometimes suggestive of chloroform or ether. It is doubtless due to the formation in the blood of a peculiar poison, believed by some to be acetone. Uremia may occur as a complication of diabetes, but does not account for the diabetic coma. Cholestatic coma is chiefly seen in the so-called "grave jaundice," and is believed to depend upon the accumulation in the blood of the excrementitious element cholesterine, a product of the disassimilation of nerve-tissue. Death, with or without convulsions, is the usual result. Anæmic coma is oftenest seen in pernicious anemia. In its clinical features it closely resembles diabetic coma. It is believed by some also to depend upon a condition of acetonæmia. Owing to deficiency of red corpuscles, the process of tissue-oxidation is imperfectly carried on, and the production of toxic substances is thereby rendered probable. Coma dyspepticum is a rare affection, believed to result from poisonous gases, acids, or ptomaines, formed in the gastra-intestinal tract.

The coma is usually preceded by dyspeptic pheno-

mena, muscular weakness, headaches, and joint-aches. The peculiar fruity odor of breath and urine, common in diabetic coma, is present. Gradual recovery often occurs, after from two to four days of unconsciousness. Closely related to this form of coma is that associated with the presence of septic, decomposing pus in natural or artificial cavities of the body.

Mention has been made of the presence of coma in a variety of diseased conditions, believed to result from the presence in the blood of poisons of autogenous origin. It may be sufficient now to simply suggest the frequent occurrence of coma, as the result of poisons introduced into the system from without, most notably alcohol, opium, chloral and cannabis indica.

The main object of this paper is to collate and compare, chiefly as to clinical history, the four typical forms of apoplectiform seizure, namely, the hemorrhagic, the embolic, the congestive, and the uremic.

I. THE HEMORRHAGIC FORM.

In the discussion of this variety of apoplectiform seizure, I shall not include the minute diagnosis of hemorrhage in the rarer, possible localities of the brain, but shall, for present purposes, assume it to be in its usual site, in and about the basal ganglia, involving the nucleus caudatus, the internal capsule, the nucleus lenticularis, the optic thalamus, and the immediately adjacent parts. A probable explanation is that these parts receive their blood-supply through large and directly penetrating branches of the anterior, middle and posterior cerebral arteries, with high intravascular tension. The walls of the small vessels are often the seat of atheroma and endarteritis deformans. Military aneurisms, of size from that of a millet-seed up to that of a pin-head, form and burst. The hemorrhage occurs in two forms, the capillary, with its separate fine red dots, and the focal, or clot form, the clot being sometimes no larger than a pea, and sometimes occupying the greater part of a hemisphere. The lateral ventricle is often opened into. The traumatic injury inflicted upon the brain-tissue; the anemia induced by clot-pressure; the clot-changer resulting finally in a mere pigmented cicatrix, with or without the intervention of a cyst; and the later secondary lesions of descending generation, involving the crossed, and, in less degree, the direct pyramidal columns of the cord, must not be forgotten.

In connection with the question of causation, let us keep in mind, that so constantly present double ultimate cause, degenerated vascular walls and intravascular pressure; the possibility of an existing hemorrhage diathesis; the age and sex most obnoxious to cerebral hemorrhage; the influence of alcohol, syphilis, gout and heredity; and the tendency of muscular and emotional strain.

The events of the clinical history of cerebral extravasation occur to the mind in a certain natural order of sequence. Thus, we have (1) the shock, (2) the period of unconsciousness, (3) the condition of the patient as he emerges from the coma, (4) the special liabilities of the first week, (5) the remaining over-symptoms, and the gradual, usually incomplete recovery, (6) the later phenomena of descending degeneration of the pyramidal columns, and (7) the special liabilities of the patient in subsequent life.

The popular term "shock of paralysis" is an entirely natural and appropriate one. The sudden depression

¹ Read at the Annual Meeting of the Association of American Physicians, Washington, May, 1890.

of the vital functions, which the word shock implies, is coincident with the vascular rupture, and the amount of shock must bear some proportion to the size of the artery ruptured and the amount of injury inflicted upon the brain-tissue. Sometimes the primary shock is comparatively slight. The patient may feel confused, or even fall, but quickly recovers himself in a measure, and is able to talk intelligently till advancing coma finally overcomes him. The elements of shock and coma are so related and combined in these cases, that it is impossible to draw a sharp line of separation. The apoplectic invasion is sometimes absolutely abrupt. A man feeling at his best, engaged in brilliant conversation, or dexterously performing some delicate operation, may fall to the floor unconscious, about as suddenly as if he had received a heavy blow upon the outside of his head. In another case the coma may be gradual and progressive development, an hour being occupied in the process.

In such a case the blood escapes slowly from the vessel, or there may be several successive bleedings of only moderate amount. The coma is largely due to the suddenness of the pressure exercised by the extravasated blood. It may, therefore, be more profound and protracted in proportion as the effusion of blood is larger and more rapid. Sometimes the seizure is preceded for days, or hours, by disordered sensations of the head, such as headache, dizziness, a sense of fulness, or flushing of the face. Occasionally an attack occurs during sleep, and the patient is found unconscious and hemiplegic.

The face is usually red or livid, but exceptionally it is pallid. The breathing is generally slow and stertorous, and its rhythm is broken and irregular. If the coma be profound the lips and cheeks are flaccid, and the latter are puffed out in expiration. The condition of the pupils varies. Most often, perhaps, they are dilated, but they may be contracted, or of natural size. Some disparity between them is not unusual. The face is often twisted, the angle of the mouth being drawn toward the non-paralyzed side. The pulse is not constant in character, but is often full and hard. Vomiting is common at or soon after the seizure. The body heat, which is often reduced one to two degrees at first, usually reaches several degrees of elevation within twenty-four hours. Even in the stage of coma the existence of hemiplegia can frequently be recognized. Slight unconscious movements of the limbs, on one side, occasionally occur, while those of the opposite side are absolutely motionless. The muscles of the paralyzed side are usually limp and flaccid, but are rarely in a state of tonic rigidity, the latter condition being specially related to the bursting of effused blood into the lateral ventricle. Convulsive movements are rare unless the motor cortical region is involved. Conjugate deviation of the head and eyes towards the side of the hemisphere involved, is occasionally present, especially when the severer lesions exist.

The coma is usually recovered from within a few hours. Exceptionally death occurs, in from a few hours to a day or two, the coma persisting to the end. In these cases the cardiac and respiratory centres of the medulla are presumably involved in the hemorrhage. As a rule, if no improvement in the coma occur within eight or ten hours, it grows more profound up to a fatal issue. Death occurs by apnoea, or by blunted apnoea and asthenia.

The mental condition of the patient emerging from the stage of coma is dull and apathetic. He asks no questions. He expresses no surprise. He seems to be utterly devoid of recollection or conception pertaining to the experience he has just passed through. In this respect the condition is in marked contrast with that of one emerging from the influence of ether.

The special liability of the first week is to the occurrence of inflammation of the brain-tissue around the clot. The cerebritis manifests itself by fever, headache, delirium and spasmodic contractions of the paralyzed muscles. In the worst cases convulsions may occur, and death by coma, but in the great majority of cases, the inflammation subsides in the course of a few days.

With the full recovery of consciousness comes the opportunity to the physician to take competent note of the remaining-over symptoms, and to "estimate the damages." The most common of the persistent symptoms of hemorrhagic apoplexy are hemiplegia, aphasia, and impairment of mental power. So far as these are permanent, they are the result of the primary traumatic injury inflicted upon the brain-tissue at the moment of extravasation, and which is finally represented by the apoplectic scar or cyst. These are the direct focal symptoms. Then there are indirect focal symptoms, resulting from temporary conditions, such as clot pressure, oedema, etc. These indirect symptoms disappear in the course of days, weeks, or a few months at farthest.

The *hemiplegia* is the most important and constant of the persistent symptoms. It is present in a large majority of the cases. The muscles ordinarily involved, are the muscles of the upper and lower extremities, and of the nose, cheek and mouth. The trapezius muscle is often paretic, inducing sagging of the shoulder. The respiratory muscles of one side may also be paretic, and marked disparity in the amount of respiratory play on the two sides may be noticed, especially in forced breathing. These paralyses are all on the side opposite that of the hemorrhage. The motor function is solely, or chiefly affected. That of sensation is usually little, if at all involved. There is great variety in the degrees of completeness of the paralysis. It ranges between absolute loss of motor power and mild paresis. The upper limb is, as a rule, much more seriously affected than the lower. There is wasting of muscle even in the early weeks. It is the direct result of the brain-lesion and is in some proportion to the degree of paralysis. It is an atrophy of disease. It is in marked contrast with the extreme wasting, with associated degeneration of tissue, of later occurrence. Reflex movements occur, especially in the lower limb, even when the motor paralysis is complete. The tendon-reflexes are exaggerated, while the skin reflexes are reduced. Electro-muscular contractility is maintained. So also is the direct mechanical excitability of the paralyzed muscles. The pulse is observed to be smaller on the affected side. The temperature is reduced. The natural color of the skin may be replaced with a purplish hue. Distention of the veins and oedema may be present. The nail-growth, as pointed out by Weir Mitchell, may become arrested. Temporary irritative contractures may occur. There is a tendency to bed-sores, especially over the trochanter and the nates of the paralyzed side, in severe cases.

The facial paralysis is usually on the same side as that of the limbs. It affects only the parts supplied

by the lower division of the facial nerve, the nose, cheeks and mouth. The expression of the face is lost. The twist is sometimes very pronounced. In other cases it is only noticeable when the patient laughs or cries. The tongue, when protruded, points to the disabled side, the geniohyo-glossus muscle, on that side, being paralyzed. The muscles of the palate may be affected. Ptosis and strabismus are occasionally present on the side opposite that of the paralyzed limbs.

Aphasia is sometimes the prominent symptom. The power of speech may be absolutely gone, or, it may be greatly modified and restricted. The memory of words may be partially or completely lost from the mind (amnesic aphasia), or, the power of articulate speech only may be wanting (ataxic aphasia). There may be a stumbling over syllables, so as, for instance, to call a widow a window (literal ataxia). The mental association of individual ideas with particular words may be broken up, leading to the indiscriminate use of words (paraphasia). There may be word-deafness, so that the vernacular may sound to a person like a foreign, and unknown language; or word-dumbness, the person being unable himself to call up words, while quite competent to comprehend words spoken by others. There may be the coining of a single meaningless phrase, which is made use of on all occasions, and for all purposes of expression (monophasia). Modifications of speech-power appear in every conceivable form, and with every possible limitation. The allied disturbances of agraphia, anamnia and alexia are often associated with aphasia. Abstractly speaking, aphasia and mental imbecility are entirely distinct affections, but I think the former can hardly exist, in any considerable degree of development, without some association of the latter.

An interesting case of monophasia occurred in my practice some fifteen years ago. The patient was a man not far from forty-five years old. A week before he had experienced an apoplectic shock. He had right-sided hemiplegia and aphasia. He had been lifted up into an arm-chair. His vocabulary consisted of three words, "yes," "no" and "boudeegy." His wife proposed that he should read me his favorite hymn, and he read with great animation and satisfaction four verses, as follows:

Boudeegy, boudeegy, boudeegy, boudee,
Boudeegy, boudeegy, boudee,
Boudeegy, boudeegy, boudeegy, boudee,
Boudeegy, boudeegy, boudee.

He looked up at me eagerly for sympathy in the sentiment. I saw him repeatedly within the next few months. The hemiplegia passed off. His health was restored. The aphasia remained. Ten years later I met him in the car. He greeted me with a warm shake of the hand, a bright expression of the face, and the single word "Boudeegy." He introduced me to the gentleman sitting beside him, "Boudeegy, boudeegy." "Glad to know you, Mr. Boudeegy," said I, and we shook hands cordially. He had opened a village store, and was engaged in successful business. He controlled affairs. His clerk did most of the talking. He had added, as I learned, one word to his vocabulary. Under extreme provocation he would say "damn." Last summer I met his old physician, who told me there had been a religious revival in the village, our patient had become interested, and had left off saying "damn." He had

reduced his scanty vocabulary twenty-five per cent. for conscience's sake.

Aphasia is sometimes, though rarely, present without hemiplegia or coma. It may constitute the only obvious manifestation of a slight cerebral lesion. I saw an instance of this sort a few years ago. The patient was a lady about seventy years old. She had suddenly lost the power of speech. There were no associated phenomena. Her intelligence was perfect. Her natural manner, which was peculiarly sprightly and attractive, had lost nothing of its individual charm. She was speechless. That was all. The aphasia lasted some six weeks, when one morning she astonished her son-in-law, who had entered her chamber, by remarking "Charles, that's a match-box on the mantel. I've been trying to get hold of that word for a month." The recovery was as complete as it was sudden. The cerebral lesion in this case must have been slight. Was it hemorrhagic, embolic or thrombotic, which?

Impairment of mental power is a frequent permanent result of hemorrhagic apoplexy. Even in instances spoken of as perfect recoveries, it may well be doubted whether the full original power of achievement and endurance is regained. There generally results a weakening of the will-power, while the emotions are excitable and less easily controlled, and the temper is irritable and moody.

In the lighter cases of cerebral hemorrhage improvement soon begins. The indirect focal symptoms promptly disappear, and those directly resulting from the primary brain injury may gradually diminish, until, in the course of two or three months, the patient may consider himself as perfectly recovered. The sensibility returns first, and often very quickly. The facial paralysis may rapidly diminish, or disappear. Improvement is earlier, and more complete in the lower than in the upper limb.

In the severer cases, when a fatal result does not occur within the first week, the paralysis, aphasia and mind-weakening may become permanent. The hemiplegia is likely to be more considerable and permanent in proportion as the primary injury to the internal capsule is more extensive. The hemiplegia gait is peculiar. The body is inclined upon the strong limb, while the paralyzed limb is dragged after it, with a tremulous jerk and swing, the depressed toe causing a continual liability to trip.

Later in the history of cerebral hemorrhage attended with persistent paralysis, permanent contractures of muscles occur. These affect the upper more than the lower limbs. Associated with them are marked atrophy and tissue-degeneration. Some authorities, notably Charcot, attribute these changes to a descending degeneration of the pyramidal columns of the cord, while others regard them as "passive contractures," resulting, like the permanent paralysis itself, from the primary injury of the pyramidal tract. As pointed out by Weir Mitchell, "post-hemiplegic chorea" often involves the paralyzed muscles.

Persons who have had one attack of cerebral extravasation are very likely to have repeated ones. The degenerative process in the vessel-walls is progressive. Each seizure is more likely than the preceding one to end fatally, and each one if not directly fatal, entails new degradation of vital power. Death by coma comes about in this way, or some intercurrent disease carries off the patient.

II. THE EMBOLIC FORM.

The middle cerebral artery, oftener the left, is the usual site of brain-embolism; rarely the internal carotid, or the basilar artery. Embolic softening, when it occurs, involves, in the great majority of cases, the same parts usually involved in cerebral hemorrhage, including the internal capsule and the great central ganglia. The first direct effect is anemia of the brain-tissue usually supplied by the plugged artery. If no relief be afforded by the establishment of collateral circulation, within twenty-four hours, the process of necrobiosis commences. Fatty degeneration and softening occur, and the tissue perishes. If the injury inflicted upon the brain be not too extensive, and the patient lives, the dead matter is removed by absorption, and may be replaced by a cyst, or cicatrix, as often seen after cerebral hemorrhage.

If the emboli be infectious, or gangrenous, gangrene or abscess may be expected to follow. The chief sources of the emboli are endocarditic and atheromatous deposits upon the mitral and aortic valves, and thrombotic deposits upon the walls of the aortic and large arteries at the base of the brain, and aneurism of the aorta.

The clinical history of the embolic form of apoplexy bears a very close resemblance to that of the hemorrhagic form. Indeed in some cases, a positive diagnosis between them is impossible.

The primary shock is the same in kind in both cases. The onset is sudden and absolutely without warning. There are none of the cerebral premonitions so often present in hemorrhage of the brain. When vascular and nutritive lesions exist in the brain, it is only a matter of coincidence. The embolus is of other and distant origin.

The intensity of the shock varies greatly in different cases. There may be only slight confusion of mind, or there may be profound coma. In perhaps half the cases, coma is absent. The unconsciousness, the stertor, the slow pulse, the vomiting and the immobility and irregularity of pupils may all be present, but they are not so frequently present, nor, as a rule, so pronounced as in hemorrhagic apoplexy. Exceptionally, the primary shock is slight, and the coma is more gradually developed, as if the emboli were small, and required reinforcement, by the formation of a thrombus about it, before becoming competent to produce marked effects. The coma is not usually so long continued as in extravasation, and instances in which it remains till a fatal issue, are very rare.

The symptoms remaining-over, after the passing-off of the coma, are the same in the embolic as in the hemorrhagic form, namely: hemiplegia, aphasia and impairment of mental power.

The hemiplegia is the most constant symptom. The paralysis is usually on the right side of the body, always on the side opposite that of the brain lesion. The upper limb is usually more affected than the lower. Involvement of a single limb only is less frequent. The face may, or may not be involved. The paralysis may be permanent, as is so often the case in extravasation, but more frequently it is quickly and sometimes completely recovered from. Great individuality is given to cases by varying combinations of the four essential elements of shock, coma, paralysis and aphasia.

Aphasia is present, in association with hemiplegia, with great frequency. It may occur in any of it

forms and in any degree of development. It may also occur as an almost solitary symptom, without the association of either coma or hemiplegia. In such cases prompt and complete recovery often ensues. The anatomical basis may be some slight thrombotic, rather than embolic, lesion. Epileptiform convulsions are said to exist more frequently, as a complication, in embolism than in extravasation.

It is doubtful whether organic aphasia, any more than extravasation, ever exists without some resulting permanent loss of mental and physical power. The degree of such loss varies with the extent and location of the cerebral lesion. It is never so great from embolism as from extensive hemorrhage.

When recovery has been made from a first attack of cerebral embolism, resulting from chronic cardiac or vascular disease, the permanent liability of a repetition must remain.

In making the differential diagnosis between embolic and hemorrhagic apoplexy, the following-named circumstances would have weight as pointing towards embolism, namely: (1) absence of cerebral prodromic symptoms, such as vertigo, headaches, face-flushing, etc.; (2) history of pre-existing cardio-vascular disease; (3) co-existing embolism of other organs, as retina, or kidney; (4) the occurrence of hemiplegia alone, without sudden loss of consciousness; (5) lightness of shock; (6) rapidity and completeness of recovery; (7) early life.

III. THE CONGESTIVE FORM.

The pathological basis, in this form of seizure, is distension of the cerebral vessels with arterial blood. The actual state of the affected brain-tissue is that of anemia, from pressure of the distended arteries. Passive congestion of the brain, in which the veins and sinuses are crowded with venous blood, as the result of cardiac, or other form of obstruction, is not direct primary cause of apoplexy. It produces it sometimes indirectly by favoring the occurrence of hemorrhage.

Circumstances predisposing to arterial cerebral congestion are general plethora, a sanguine temperament, a short, thick neck, and the age of early maturity. The most common exciting causes are excessive muscular, mental and emotional activity; pure, non-compensatory hypertrophy of the left ventricle of the heart; over-feeding, with lack of exercise; alcoholic over-stimulation; and vaso-motor influence. Obstruction to the natural flow of blood in the arteries of the organs and parts may also lead to excessive flow into the arteries of the brain.

Prodromic symptoms are quite constant, such as headaches, a sense of cerebral fulness and throbbing, noticeable beating of the carotid and temporal arteries, flushing of the face and eyes, heavy heart-action, asympnia, mental confusion, nervousness and irritability.

The seizure is marked by shock and unconsciousness, as abrupt, and often as pronounced as in extensive hemorrhage into the brain. The face is flushed, the eyes are injected, the pupils are contracted, the pulse is full and bounding, the breathing is heavy and stertorous, and the throbbing of the carotid is visible, as well as palpable. There are no unilateral phenomena.

If prompt and judicious administration be made of sedative and depletive treatment, relief is usually

quickly obtained. The liability of vascular rupture and extravasation constitutes the chief danger. The recovery may be complete, but the necessity of careful regulation of the diet and regimen, with a view to prophylaxis, is imperative.

The congestive form of apoplexy is distinguished from the hemorrhagic and embolic forms by the distinctive group of symptoms connected with the seizure, and by the absence of the remaining-over symptoms, hemiplegia, aphasia, and impairment of mind. It is separated from the uremic form by the absence of albumen and tube-casts from the urine, and its freedom, as a rule, from the convulsions so common in uremia. The differential diagnosis from alcoholic coma would be helped by the exclusion, both from history and environment, of everything suggestive of alcohol.

IV. THE UREMIC FORM.

The anatomical basis in this affection is the contracted kidney, or the kidney of diffuse chronic nephritis.

The essential pathological condition is toxæmic. There is an accumulation in the blood, and also probably in the tissues, of urea, or at least of some one, or more, of the excretitious products of tissue-metabolism, of which urea represents the final stage, which are normally thrown off in the urine.

The coma of uremia is sometimes gradually developed, without sudden attack. In other cases coma occurs with apoplectic suddenness. It is only with the latter class of cases that we are now concerned.

These may be prodromic phenomena, such as headache, dizziness, dyspnea, dyspepsia, edema, or a fleeting sensation, as if about to faint. But the seizure is abrupt, with marked shock. A man of early or middle mature life, of pale complexion, and contrasting in physique with a subject of congestive apoplexy, who has never thought of himself, or been regarded by his friends as a sick man, is suddenly stricken down. Later, in retrospect, friends may be able to recall little circumstances indicative of slight impairment of vigor and elasticity of mind or body, which did not at the time arrest their attention. The coma is profound. The face is pale, and often covered with cold sweat. There is stertorous breathing, and the pupils are dilated.

In the great majority of cases the coma is preceded by, or accompanied with, convulsions. These are epileptiform in character, with frothing at the mouth, and biting of the tongue. The convulsions may be repeated at longer or shorter intervals, and death may occur within two or three days, with no recovery of consciousness; or, the coma being less profound, consciousness may be recovered, and weeks or months may elapse before the occurrence of the final and fatal seizure. During this interval the characteristic anemia of chronic Bright's disease may become rapidly developed.

Hemiplegia and other symptoms, which characterize cerebral extravasation and embolism, are usually absent. So also are the peculiar physiæque, the flushed face, the injected eyes, the contracted pupils, the full, bounding pulse, and the other characteristic symptoms of active cerebral congestion. The finding of albumen and tube-casts in the urine, which should be early drawn by the catheter and tested, completes and establishes the diagnosis.

TREATMENT OF UTERINE FIBRO-MYOMATA BY ABDOMINAL HYSTERECTOMY.

BY J. C. IRISH, M.D., LOWELL, MASS.

THAT there are some cases of uterine myomata, in the treatment of which hysterectomy is our only resource, very few will question. But we shall find a very wide divergence of opinion as to the extent or frequency with which this operation for radical cure should be advised or is justifiable.

The high rate of mortality that attended abdominal hysterectomy for fibroids, until very lately, explains in part the small degree of favor still accorded by many to the operation. Again, a just estimate of its value and necessity is prevented by some vague and erroneous notions as to the progress of myomata, the suffering they cause, and the fatality that attends them. Thirdly, certain palliative modes of treatment are offered as substitutes for hysterectomy, which are claimed to be so efficacious as to obviate all necessity for the latter operation, except in very rare instances.

Therefore, in considering the treatment of uterine fibroids, we have the radical method, hysterectomy, to compare with the palliative methods, namely, removal of the uterine appendages, electrolysis as taught by Apostoli, and the treatment of the endometrium by medicinal applications and the curette (this third method being directed to the relief of that prominent symptom, hemorrhage).

But before making any comparison between the treatment for radical cure and that for palliation, an inquiry as to the tendency and natural history of these abnormal growths will aid us very much in assigning to each method its relative and exact value.

The different terms, fibroma, myoma and fibro-myoma, used in describing these tumors of the uterus, indicate no very marked distinctions from the standpoint of the pathologist. Histologically they are composed of unstriated muscular fibre and connective tissue in varying proportions, precisely as is the uterine structure, and they differ from the latter merely in the relative proportions of the two kinds of tissue.
